The trouble does not generally come on suddenly, the patient complains that his knee has begun to pain him and that he has discovered a bump there. If one inquires carefully into the history of such a case one almost always elicits the fact that the first time pain was felt was after some severe exertion—e.g., a long or a high jump, &c. Ever since the pain has always been present on any severe exertion. The trouble has gradually become more and more pronounced, especially if the patient has continued to take part in games and sports. At last even ordinary walking brings on pain; the patient himself and his relations grow anxious and he is taken to see a medical man. All these symptoms, which seem to be against the theory of a traumatic injury, are now satisfactorily explained by the Roentgen pictures. That the injury is productive of so little discomfort at the time depends no doubt upon the fact that the fracture of the trunk-like projection takes place without involving the perichondrium which covers it. And as cartilage just as little as bone is provided with nerves of sensation, it is easy to understand how such a lesion can occur without any pain at all. Meanwhile a serious weakness has been caused at the point of insertion of the ligamentum patellæ and each contraction of the extensors of the knee aggravates the condition. In this way an irritation is constantly operating which leads to an increase of the inflammatory symptoms. The patient becomes more and more an invalid. The lesion is, though not serious, very troublesome. It usually lasts six months, but two years may elapse before the patient gets a useful limb again. Much depends on the amount of anatomical disturbance and on how far the patient is careful not to irritate the injured cartilage.

As for the treatment, the first thing to be done is to have a Roentgen picture taken. If the injury is shown to be a severe one the patient should be put to bed with or without a splint. In milder cases it is sufficient to warn the patient against any violent exercise likely to irritate the parts; in these latter cases it is not necessary to forbid walking on level the coats, the lumen of some veins being occupied by pus cells; the vas deferens also presents a well-marked cellular infiltration of its mucous membrane and various muscular coats.

Ætiology.—Among the old Ceylon practitioners the disease was considered by some to be of filarial origin; others considered it to be a malarial affection. I have examined bacteriologically five cases: in all a diplo-streptococcus was present in the pus. In two cases in which I have examined bacteriologically the blood taken from a vein, the same strain of streptococcus was found in the blood. I give here a brief description of the organism.

Microscopical characters.—The coccus is arranged in pairs, or short or long chains; when arranged in pairs its shape is somewhat gonococcus-like. It is gram-positive.

Cultural characters.—Broth: In some cases general turbidity, in others a flocculent sediment is present, while the upper part of the bouillon remains clear. The same strain may at times produce general turbidity, at other times may give rise to a flocculent sediment. Peptone-water: Same growth as in broth, only less abundant. Agar: The growth may be very delicate, fairly abundant, or even luxuriant; when very abundant the colonies coalesce into a whitish creamy mass. Gelatin: Same characters as in agar, only more delicate. Milk: The milk is rendered acid and clotted. Sugar media: Glucose broth, acid; lactose broth, acid; maltose broth, no acid; saccharose, no acidity; saccharine, no acidity; mannite, no acidity; salicin, no acidity; dextrine, no acidity; Mackonkey agar, no growth. Serum media: nothing characteristic. Agglutination: using the cultures which show a diffuse turbidity it was easy to show in my cases that this streptococcus was agglutinated up to a dilution of 1 in 50, and occasionally 1 in 100, by the blood not only of the patient from whom the strain was isolated but also from the blood of other patients affected by the disease, provided the blood was not collected before the third or fourth day of the illness. This strain of streptococcus is not agglutinated by the serum of patients suffering from other streptococcal diseases, such as erysipelas.

Conclusions.—1. There is endemic in Ceylon, and probably in other parts of the tropics, a peculiar affection of the cord which it seems to me has sufficiently characteristic symptoms to be ranked as a separate disease. This affection might be named "endemic funiculitis." 2. A diplo-streptococcus is constantly found in the pus. Further investigation is needed to decide whether this diplo-streptococcus is the primary cause of the disease or, as I am inclined to believe, is merely a secondary agent playing a rôle only in the suppurative stage of the malady.

Colombo, Ceylon.

PHENOMENAL ABUNDANCE OF PARASITES IN A FATAL CASE OF PERNICIOUS MALARIA.

BY J. CROPPER, M.A., M.D. CANTAB.

(*With Coloured Plate.*)

NOTES of the case from which the figures in the coloured plate are taken were read before the Society of Tropical Medicine and Hygiene, in London on Feb. 21st last. The facts are briefly as follows:—

A Samaritan, aged about 55 years, was admitted to the C.M.S. Hospital at Nablus, Palestine, on Sept. 15th, 1907, for malarial fever contracted in the Jordan Valley, whence he had just come. On admission parasites were not more numerous than I had seen them previously in other cases—viz., two or three in a field and of the subtertian type; crescents were very few. The fever followed a tertian course and when high (103° F.), on the evening of admission sporulating forms were easily found. At 9 A.M. on the next day the temperature was down and most of the parasites were of the unpigmented ring form. Early on the second day after admission the patient was seized with algide symptoms, the temperature in the mouth being below 95°, which was raised to 97° with difficulty by hot bottles, &c. In spite of treatment, however, he never rallied but succumbed at midnight, having previously had diarrhœa; there were no cerebral symptoms and he was able to answer his name to within two hours of his death. No post-mortem examination was allowed. Most of the slides were taken from the ear two hours before he died and were principally stained by Giemsa's method.

The chief points worthy of note in the coloured plate are the following:—

FIG. 1.—*Clumping of red cells* containing pre-segmenting and more rarely sporulating parasites in masses of from three to 21, which so far as I know has not been previously observed in the peripheral blood, though it is commonly seen in the brain and other organs affected in pernicious attacks, after death. I can find no reference to this occurrence in Marchiafava and Bignami's account of pernicious malaria. I would conjecture that such masses must occur in the internal organs in intense infections, but that as a rule they are not seen, being eliminated or filtered out from the blood in the spleen or the liver, thus giving rise not only to enlarged spleen but also to bilious remittent attacks and malarial hepatitis. Where, however, other organs such as the brain, the kidney, the pancreas, or the intestinal walls are affected, cerebral symptoms, acute hæmorrhagic and pancreatitis, &c., develop, not to mention a gastric form which is often overlooked.

As quoted by Dr. G. C. Low at the meeting referred to above, it occasionally, but extremely rarely, happens that the quartan parasite undergoes enormous increase in numbers and thus may prove fatal.

In Fig. 1 can also be seen a large mononuclear leucocyte containing in its protoplasm a red cell infected by a parasite which has not yet reached the sporulating stage: as noted by Marchiafava and Bignami,[1] this only occurs with the subtertian and never in the case of the tertian or quartan parasite.

FIG. 2.—*Unpigmented rings in extraordinary numbers,* infecting from 40 to 50 per cent. of the red cells; of 500 counted at random 248 were infected and in some cases a simple red cell contained even six or seven rings.

FIG. 3.—*A polymorphonuclear cell containing spores and melanin.* This only occurs in intense infections; usually the large mononuclears are alone affected thus.

FIG. 4.—*A large mononuclear leucocyte containing three sporulating parasites.* This is very rarely seen even in pernicious attacks.

FIG. 5.—*A pigmented leucocyte containing 25 blocks of pigment or melanin.* Since each of these was the centre of a sporulating parasite, at a reasonable estimate at least 200 to 250 spores had been ingested by this one cell which has enormously hypertrophied as a result of such overfeeding. The greatest number of spores in any one sporulating body was 18 in this case, or on an average 8 to 12.

FIG. 6.—*A red cell containing three sporulating forms.* This has only once been seen in this series, though I have several times seen two. I may add that one could find no trace of the endocorpuscular conjugation described by some authors, and it would seem likely that where a red cell is infected by several rings, each parasite follows out its life-history independently of the others, even when one is a schizont or segmenting form and the other a gametocyte.

FIG. 7.—I have also drawn a series of immature crescents, differentiating the male and female forms as far as possible. The number of these increased enormously on the last day, and it would appear that on the onset of algide symptoms with the temperature under 95° in the mouth and the extremities icy cold to the touch, some sort of migration of the gametes took place from the bone marrow. In any case the occurrence of these immature forms is very rarely seen except in the bone marrow or in the blood of internal organs. The young *male* crescents are in some cases almost or quite circular and often surrounded by a zone of hæmoglobin; the chromatin may occupy any position in the cell and may even exist as a band across the "equator," as in No. 1 in the second row. The pigment is in all cases discrete and never gathered into a block, as occurs early in the segmenting forms. This is also true of the female forms which are more pointed: practically none of them have taken on the crescentic shape which is such a characteristic feature later. Figures of twin crescents and a crescent and sporulating

form in the same cell, the so-called gameto-schizont (of Schaudinn) are also given.[2]

---

[1] New Sydenham Society, p. 181.

The general condition of the blood deserves attention. There was evidently a considerable leucocytosis, though I regret that no count of white cells was made in the fresh blood. Nucleated red cells were fairly common. The differential leucocyte count is as follows: neutrophiles, 40 per cent.; large mononuclear, 21 per cent.; large lymphocytes, 26 per cent.; small lymphocytes, 12 per cent.; eosinophiles, 0·5 per cent.; and mast cells, 0·2 per cent.

Though cases of blackwater fever have from time to time been recorded from Jerusalem and elsewhere in Palestine; this is the first and only true case of pernicious malaria that I have met with amongst nearly 500 cases diagnosed microscopically, quite 30 per cent. of which were subtertian infections, in two and a half years, which strengthens my belief that a comparatively high average daily temperature is necessary for the development of pernicious attacks. Tropical *heat is rarely experienced* for long in any part of Palestine with the exception of the Jordan Valley, which is sparsely populated and chiefly by bedouin, who must be at any rate partially immune.

Chepstow.

A CONSIDERATION OF THE STATE OF THE AUTONOMIC NERVOUS SYSTEM IN ACUTE SURGICAL CONDITIONS.*

By ALBERT J. WALTON, F.R.C.S. Eng., L.R.C.P. Lond., M.B., B.S., B.Sc. Lond.,
SURGICAL REGISTRAR, LONDON HOSPITAL.

I have selected the present subject for debate to-night firstly, because it seems to me that, by giving attention to these conditions, one may best hope to decrease the present high mortality existing in cases of acute surgical lesions necessitating immediate operation; and secondly, because it is one which has excited much attention abroad but to which but little heed has been given in this country, and, in the majority of cases, the old methods of dealing with these conditions, which in light of recent knowledge would appear to be not only useless but positively harmful, are still adhered to. Two main conditions will have to be considered: (1) alterations in the vaso-motor centres with subsequent vascular changes; and (2) changes in the local nervous system of the intestines after abdominal operations.

1. Alterations in the Vaso-motor Centres.

In this category must be grouped the conditions of shock and collapse. It has always been taught that these two conditions are essentially different, but it must be remembered that although their causes may be separate, not only are they in the majority of cases associated, but the active factor—viz., a lowered blood pressure—is present in both, and may call for similar lines of treatment. This being the case, it will perhaps be best to commence with a definition of the two conditions. Those given by Lockhart Mummery[1] are as follows: "Shock is a condition resulting from a fall in general blood pressure, due to exhaustion of the vaso-motor centres." "Collapse is a condition resulting from a fall in general blood pressure, due to inhibition of the vaso-motor centres or a loss of the circulating fluids." Thus it may be said that in both cases the condition is due to a lowered blood pressure, caused in one case by a vaso-motor paralysis, and in the other by a loss of fluid. Shock is the condition with which we are now mainly concerned, but in most surgical conditions there is associated loss of blood and fluid exudates, and hence the second factor is but rarely absent.

The blood pressure in man and in animals is maintained in health by two factors: firstly, the work done by the heart; and, secondly, the size of the peripheral vessels. The first factor may be shown experimentally by stimulating the peripheral end of the vago-sympathetic nerve in the dog; the heart-beats become slower and may soon stop, the blood pressure at the same time falling. In those animals in whom the vagus and sympathetic trunks are separate stimulation of the peripheral end of the sympathetic immediately below the inferior cervical ganglion causes augmentation of the heart with a rise of pressure, whilst stimulation of the peripheral end of the vagus causes slowing of the heart with a fall of pressure. Tracings showing this may be found in any text-book on physiology.

The effects of the second factor are shown by the following experiments: That alterations may be caused by a change in the calibre of the vessels is shown by the fact that if a tame rabbit be suspended there is a rapid fall of blood pressure, so that the animal may die. If a wild rabbit or dog be used instead this fall does not take place, but if chloral hydrate be given previously, so as to destroy the controlling influence of the vaso-motor centres, these animals react in a similar manner to the tame rabbit (Leonard Hill). These changes are due to the dilatation of the splanchnic vessels, which is shown by the fact that they are readily prevented by previously applying a tight abdominal binder. The calibre of these vessels is in health controlled by vaso-motor nerves. This may be shown by stimulating the sympathetic nerve in the rabbit; this is followed by a marked constriction of the vessels of the ear on the same side. If the nerve be paralysed the vessels undergo marked dilatation. Stimulation of the peripheral end of a sensory nerve usually causes vaso-constriction of the part supplied. Stimulation of the splanchnics causes marked constriction of the vessels of the splanchnic area, with a rise of general blood pressure. The action of these nerves is controlled by a centre in the bulb. If this be stimulated directly by an electrical current there is an immediate rise of blood pressure. A similar effect follows the application of digitalis, *strophanthus*, alcohol, or strychnine, whilst opium or chloral causes a marked fall, with dilatation of the peripheral vessels.

Thus the size of the peripheral stream is in health dependent upon the action of the centre, and alterations in the blood pressure are chiefly caused by variations in the size of the vessels in the splanchnic area. These variations are brought about by the influence of afferent impulses to the centre, as may be shown thus: Stimulation of the central end of the depressor nerve in the rabbit causes a marked fall in the blood pressure, and this effect occurs after division of both vagi, and, hence is not due to alteration in the rate or force of the heart beat. Stimulation of the central end of the sensory nerves is followed by a marked rise in blood pressure, but if the stimulation be continued the centres become exhausted and the pressure markedly falls. Now in a condition of shock this latter state is present, the vaso-motor centres have become exhausted by multiple afferent impulses, the vessels in the splanchnic area are widely dilated, *and the peripheral blood pressure is low.*

Crile,[2] Sherrington,[3] Cobbett and Roy, working on the condition of shock in animals, have shown that there is a constant relationship between the fall of blood pressure and the symptoms of shock present, and *that the fall* of peripheral blood pressure is accompanied by a rise of pressure in the portal area, the blood all accumulating in this latter position.

The experiments of Crile[2] were carried out as follows. The animals used were dogs. They were anæsthetised and mercurial manometers were inserted into different vessels in the circulatory path. They were then subjected to various operations and the condition of the pressure and shock noted. After death a necropsy was held and the condition, more especially with reference to the amount of blood in the different vessels, was investigated. When subjected to severe and repeated trauma it was found that there was a primary rise in the blood pressure, soon followed by a marked fall, and when this fall reached a certain level the symptoms of shock became evident; if the trauma were continued the shock increased, the fall of pressure became more marked until it reached the zero line, and the animal died. These symptoms were not due to any cardiac influence, for they were produced after the cardiac inhibitory apparatus had been cut out by section of the vagi, and in all these cases it is not only found that the heart works as rapidly and as forcibly as is usual, but that its action is augmented in a vain attempt to maintain the pressure.

In all cases where death was produced there was a *marked* increase in the amount of blood in the splanchnic area, the fall of pressure therefore being caused by a dilatation of these vessels. In certain operations, which will be further considered presently, where the *trauma was applied* to the intestines, the vessels in the splanchnic area were seen to dilate *pari passu* with the fall of blood pressure, and with the increase of shock.

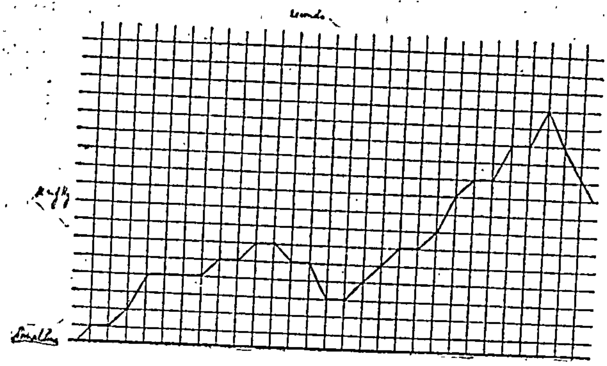
---

[2] The male crescents are seen in the top line, the last five of the lower line being female forms.

* A paper read before the London Hospital Medical Society. (The superior figures refer to the bibliography at the end of the article.)

In many cases the early part of the trauma, such as the primary incision or dilatation of the sphincters, caused a preliminary rise in the blood pressure, which was later followed by a marked and steady fall (see Fig. 1). This corresponds exactly with the changes mentioned above as following stimulation of the central end of a peripheral nerve.

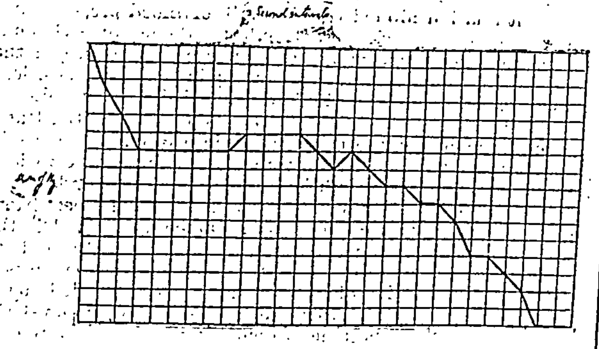
FIG. 1.



The preliminary rise of pressure with cutting and crushing the skin. [Compiled from 22 experiments (Crile, "Surgical Shock").]

In all these cases the alterations in blood pressure were due to changes in the conditions of the vessels, and that these changes were caused by impulses conveyed to the vaso-motor centres was shown by the fact that: The amount of shock was directly proportional to the amount of injury to the nerves of the part, and the more specialised and abundant the nerve-supply of a part the more did it contribute to the production of shock when subjected to injury. Thus muscles, joints, and bones without periosteum may be injured with but little alteration to the blood pressure. If the periosteum be present the fall of pressure on division will still be present. If a peripheral part, such as the paw of a dog, were cut there was but little fall of pressure; when crushed the fall in pressure and consequent shock were much more marked. When nerve trunks were injured there was a primary rise followed by a marked fall. If previous to injury the main afferent paths were cocainised, the resulting fall of blood pressure and shock were negligible however severe the trauma. In this connexion it was found that the amount of shock depended upon the part injured, and owing to the importance this bears upon general surgery it must be considered more fully. Incisions in the skin cause a primary rise, as mentioned above, followed by a fall, but in certain areas where the nerve supply is great the fall may be immediate. The most important of these are the skin of the abdomen and scrotum. Injuries to the abdominal contents cause a marked fall in the blood pressure; here there is a free nerve supply of the branches of the sympathetic, and much smaller stimuli are appreciated, so that if an animal's abdomen be merely opened and the intestines exposed there is soon a marked fall of peripheral blood pressure, a rise of pressure with dilatation of the vessels in the splanchnic area and symptoms of shock (Fig. 2). The fall in pressure could be checked by the application of warm saline solution to the peritoneal cavity. If previous to the trauma the superior mesenteric artery were clamped, the fall in pressure either took very much longer to occur or did not occur at all. Operations upon the brain were associated with a very marked fall of pressure. A similar marked fall, starting early and associated with no preliminary rise, accompanied operations upon the testicle. This could be entirely prevented by a previous injection of cocaine into the tunica vaginalis or cord.

FIG. 2.



The fall of pressure on exposing and manipulating the intestines. Compiled from 15 experiments (Crile, "Surgical Shock").

The shock produced in these experiments may therefore be regarded as being due to multiple afferent impulses passing along the nerve trunks, and it is conceivable that these impulses might cause the fall of blood pressure by one of two methods—either they might stimulate a centre so that impulses would be passed down vaso-dilator nerves, leading to an active dilatation of the splanchnic area, or the vaso-constrictor centre, which is continuously acting, might have become paralysed, and hence the vessels dilate atonically. That this latter is the case is shown by two further experiments by Crile.

When profound shock is established the centres cannot be stimulated, as they can in health, by the administration of brandy or strychnine. When the vaso-motor centres are cut out by injecting a 2 per cent. solution of cocaine into the medulla profound shock was produced, the blood pressure fell from 115 millimetres of mercury to 50 millimetres, respiration ceased and had to be continued artificially. Electrical stimulation of the sciatic nerve and injection of strychnine caused no rise in pressure. A similar result was caused by destroying the centres by pithing. In addition to these changes in pressure due to alterations in the size of the vessels in the splanchnic area there are in animals alterations in the blood itself which probably greatly help to bring about this fall of pressure and point to a line of treatment which, as will be shown later, has proved to be most efficacious.

The experiments of Sherrington and Copeman[3] have shown that operations, especially those involving exposure of the peritoneum, upon healthy animals are followed by a loss of fluid from the blood and a rise in the specific gravity. In one experiment this rose from 1·054 to 1·062 in 15 minutes. This condition has been found to last for several days and then slowly passes off. In cases of burns or other lesions causing a large destruction of the skin it is well marked and probably occurs by evaporation. Since by this means the total amount of blood is decreased the pressure will obviously fall, and the increased viscosity with subsequent rise in friction will tend to the formation of thrombi, and Watson Cheyne has shown that in such cases coagulation may occur in the pulmonary vessels. Although the amount of blood is decreased, absorption of fluid in shock is greatly delayed (van Engleman), which has been thought to be due to an arrest of metabolic processes.

Shock, then, in animals may be defined as a condition of decrease in blood pressure due to vaso-motor dilatation of the splanchnic areas, which dilatation is caused by multiple impulses passing along the afferent nerve paths; these impulses at first cause an increased action of the centre, which is soon followed by paralysis. The condition is assisted by a decrease in the total amount of the fluid constituents of the blood. In man the conditions are much more difficult to determine; operations cannot be carried out in the same experimental way, hence the amount of shock cannot be regulated and the required factors cannot in all cases be introduced.

The blood pressure cannot, of course, be determined and accurately recorded in the manner undertaken with animals, and hence some other method has to be utilised. Many instruments have been devised for this purpose, but it may at once be said that the Riva-Rocci has been proved clinically to be quite satisfactory. The instrument is now well known and consists of a rubber bag, which is strapped round the limb by a leather band; from it passes a thick rubber tube leading to a mercurial manometer. The bag can be pumped up by a rubber ball with valves. When it is partially blown up the mercury is seen to oscillate with the pulse-beats. Either the systolic or diastolic pressure may be obtained by its use. The simplest to record and the less liable to error is the former; to obtain it the pressure in the bag is increased until the oscillations just cease; the pressure is then lowered until the mercury just begins to oscillate again; the mean of these two readings of the manometer is taken and corresponds to the systolic pressure. The diastolic pressure corresponds to the point at which the oscillations are at their greatest. The mean blood pressure is that which is required for a most accurate understanding of the patient's condition, and it can be deduced from the above. For clinical purposes, however, the systolic pressure is sufficient. In taking any readings with it the patient should be kept horizontal to avoid any alterations in pressure due to change of position. This method is very simple, and after a short trial accurate readings may be taken by an intelligent nurse. The readings of this instrument have been carefully compared—first, with the readings of manometers in the vessels of animals (Lockhart Mummery)[1]; and, secondly, in the dead, on limbs artificially injected with a known pressure—and the margin of error has been found to be very small.

A large number of experiments have now been made in man with this instrument, and it has been found that in health there is a slight change in pressure when the position is altered. If the reading be taken from the arm there is a slight fall owing to the action of gravity when the patient is placed upright. This is very slight owing to compensation by the vaso-motor system. In disease this is markedly increased, as is well shown clinically by the tendency to syncope when a patient first assumes the erect posture after an exhausting illness. In many diseases, more especially those in which there is considerable irritation of areas well supplied with nerve terminals and those associated with a loss of fluid, there is nearly always a marked fall. An example which more immediately concerns us here is acute general peritonitis, where there is a steady fall before operation is commenced. That the pressure is markedly low in Addison's disease has been known for long and will demand our further attention when the treatment of shock is considered.

The condition of the blood pressure has now been carefully investigated in many operations in which shock has been produced. Cushing and others have recorded many cases where the above instrument was used, and it may be stated that in man the blood pressure has been found to react in these cases in a manner similar to that of animals subjected to experiment. Thus it is seen that, as in animals, the amount of shock and the fall in pressure are proportional to the amount of nerve injury. Lockhart Mummery[1] records a case of excision of the breast where there was much traction upon the brachial plexus; in this case the pressure fell from 135 to 60 millimetres of mercury. In all cases of operation upon acute abdominal conditions the fall is very marked, and, as mentioned above, in these cases the condition itself, apart from operation, causes a considerable fall, hence it is that these cases form so large a percentage of the deaths that occur in any surgical ward. In accidents associated with much laceration of the soft tissues the shock is considerable, and they correspond with the cases of experimental crushing of a limb in animals recorded by Crile. In many cases, as in animals, the primary incision or early stimulation of an afferent nerve trunk is accompanied by a rise in pressure; as the stimulation is continued the pressure begins to fall.

The course of events may then be looked upon as a primary stimulation of the centres, with vaso-motor contraction and consequent rise of pressure. The centres now become over-stimulated and are exhausted, the vessels dilate and the pressure falls. An attempt is made to maintain it by an increased rate of the heart beat, and the pulse is found to be rapid. In time the dilatation is such that the pressure cannot be maintained by the heart alone and steadily falls until either the centres recover or the patient dies.

Such, then, is a brief outline of the methods which have led to the present state of our knowledge of shock in man, and it may now be accepted that the state is one of exhaustion of the vaso-motor centres, which state is brought about by severe afferent impulses, and which manifests its symptoms by a fall of blood pressure, with ultimate loss of nutrition to, and function of, the vital centres in the brain and cord. In any severe operation in man there are other factors, however, apart from the mere trauma, which tend to keep up or produce the condition, and these will now have to be considered.

The length of the operation.—As long as the operation continues, the centres will be getting more exhausted and the condition of shock will be increasing. The clinical recognition of this fact is well seen in cases of intussusception in children, where it is well known that the hopes of success depend, to a very large measure, upon the rapidity with which the operation can be completed. In a large number of cases, however, the introduction of asepsis and anæsthetics has tended to abolish the old methods of rapidity, and operations were undertaken which often lasted for some hours. Of late years the importance of this fact has been recognised, with the result that operations are more rapidly completed, quicker methods having, with an advance of knowledge, been introduced. The length of time occupied by the operation is of increasing importance where the condition of the patient is poor. Elderly people, those who have previously been ill-fed and subjected to hardships and those who have undergone a long and trying illness, will fail to maintain their blood pressure even for a short time.

In acute abdominal conditions the centres are being exhausted before the operation is commenced, and thus the length of time that the surgeon has at his disposal during the course of the operation will decrease *pari passu* with the length of time the condition has existed previously, so that in these states the prognosis will almost wholly depend upon the time the patient has been affected before advice is sought. In children this factor is even more important, for in them the different stages are more rapidly passed through, and the stage of shock is sooner reached. In a similar manner the amount of trauma will influence the subsequent fall, and delicate tissues such as the intestines should be exposed and manipulated as little as possible during the course of an operation.

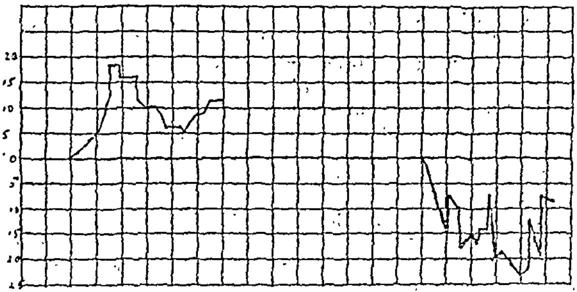
Anæsthetics.—The action of anæsthetics in regard to shock has to be considered from two points of view. Firstly, by producing unconsciousness the effects of the afferent impulses are markedly decreased. Not only are the higher centres of consciousness unable to appreciate the trauma, but the lower reflex centres are not so markedly affected, and the condition of syncope, which would increase the shock, is decreased or absent. Hence, with all anæsthetics the shock tends to be less than without them. On the other hand, they may themselves be toxic in their action on these centres, their absorption tending to an early exhaustion of them. The different anæsthetics vary greatly in these respects.

Ether.—With this drug it is found that there is a preliminary rise in the pressure which is maintained throughout the whole course of the operation, and any fall which occurs is due to the operation alone (Cook, Briggs, Blauel, Mummery). Hewitt[5] describes two forms of surgical shock, one of which, the respiratory, occurs early in the course of anæsthesia, and is more marked with those having some respiratory obstruction; hence, presumably, it would be more marked with ether than with chloroform anæsthesia. This form of shock, however, occurs only during the course of the anæsthetic, and is a totally different condition from that which we are considering now; it certainly causes no lowering of the blood pressure. The absence of shock is not in these cases due to any stimulant effect of the drug, for, as has been pointed out, when shock is present the centres absolutely fail to react to any form of stimulation; in fact, stimulants only further exhaust the centres and aggravate the condition.

Chloroform.—This, on the other hand, is accompanied by a steady fall of blood pressure throughout the whole course of its administration (Hewitt,[5] Blauel, Crile[7]). Hewitt, speaking on this point, says that all physiological blood tracings show a steady fall with chloroform and that shock (his second variety or circulatory shock) occurs late, when the anæsthesia is deep; of his series of 71 cases, 59 occurred when chloroform or a chloroform mixture was being administered, and he states that "as to anæsthetics under which circulatory shock is most common there is no doubt that chloroform is, *par excellence*, the agent which specially predisposes to this condition, owing to its power of reducing blood pressure." The different effects of the two anæsthetics is well shown by Blauel's chart (Fig. 3), calculated from 25 cases of ether and 18 of chloroform, all in cases over 20 years of age and with an anæsthesia of 50 minutes. Hence it may be stated that with ether the blood pressure is well maintained, whilst with chloroform there is a steady fall.

Spinal anæsthesia.—Of late years this method, which, by the introduction of a local anæsthetic within the spinal membranes, causes paralysis of the sensory cells and complete anæsthesia of the part supplied by these nerves, has been much used. A series of 200 cases have now been recorded by Barker,[4] and a full description of the methods of using it may be found in his papers. Novocaine, stovaine, and tropacaine have all been used for this purpose and the difficulties and dangers associated with their early use have now been overcome with a more intimate knowledge of the dosage, &c.

FIG. 3.



Blauel's chart of the blood pressures with ether and chloroform anæsthesia. (L. Mummery, "Physiology and Treatment of Surgical Shock and Collapse.")

It has been shown that spinal anæsthesia does not, *per se*, cause the slightest fall in blood pressure, and that operations performed by this method, even in old and much exhausted people, are accompanied with remarkably little shock. About 0·05 gramme of the drug (stovaine) should be used. Many objections have been raised against it, but these would seem to be rather more sentimental than real and present results would point to this method occupying a prominent position in the future in the treatment of emergency surgical conditions.

The loss of blood and other fluids.—The loss of fluids does not actually produce shock but a condition of collapse. As, however, the symptoms in either case are due to the fact that the higher centres are not supplied with blood, it follows that a condition of shock is more likely to be brought about when the loss of blood is great, the dilated splanchnic area containing a relative greater amount of the fluid left. The same argument would, of course, hold good where there is a large amount of inflammatory fluid exuded, and this factor is probably an important one in cases of acute general or diffuse peritonitis, and is one of the causes of the early appearance of shock in these cases, although doubtless the result is more largely caused by toxic factors acting directly upon the centres.

It has already been pointed out that operations upon the head are often accompanied with severe shock. Now, these cases are in the majority associated with considerable hæmorrhage, and there is undoubtedly a close relationship between the two, as is seen by the fact that when precautions are taken to prevent this hæmorrhage, as will be described presently, the amount of shock will be greatly decreased.

TREATMENT.

The main causes of shock, direct and indirect, having been mentioned, the preventive and curative methods of treatment may now be considered.

(a) *Preventive.*

The greater number of these cases are emergency conditions, in which a certain amount of shock is already present, and thus, unfortunately, but little can be undertaken in the way of preventive measures. In other cases much may be done to increase the patient's resistance; and, what is more important, much may be left undone which under mistaken ideas was formerly very prone to bring about this condition.

In the preparation for operation drastic purgatives should not be given; these, by producing a temporary watery diarrhœa, cause a fall in the blood pressure; this is more likely to be the case in operations upon the rectum, and as the older methods, such as Kraske's operation, are still occasionally undertaken and are accompanied by a great deal of shock, this is specially to be avoided. The method now adopted as a routine in this hospital will be found the most useful in this respect. Either two nights or the night before the operation one dose of a purgative is administered, next morning an enema is given, and thus the bowels are only opened once or twice, and incontinence during operation is also avoided.

As regards *dieting previous to operation*, too much may be done from a fear of post-anæsthetic vomiting, but I feel certain that this is a fear which has been much exaggerated. One constantly sees cases in which no food has been administered for eight hours before an operation and yet vomiting occurs, the vomit containing undigested solid food; and it would seem that, under the fear or apprehension of the approaching operation, the progress of digestion is greatly retarded; therefore, to avoid this vomiting, no food would have to be given for a period which would be too long for practical purposes. Moreover, in the majority of these cases no harm follows the vomiting, and death or inconvenience is rare. It is a noticeable fact that when post-mortem acid digestion of the lungs is found nearly all the cases are those of general peritonitis and do not occur with simple anæsthetic vomiting; and if one regards such changes as due to the inhalation of gastric contents, as appears most probable, it would seem as if the bad effects of vomiting on the respiratory system only occur with the more severe type found in peritoneal affections.

The following figures taken from the records of this hospital are of great interest from this point of view:—In the period of 14 months (Jan. 1st, 1907, to March 1st, 1908) the total number of anæsthetics administered was 18,639. In the same period the total number of cases showing acid digestion of the lungs post mortem was 47. The number of these that had been operated on was 26. Of these general peritonitis was present in 21. Of the remaining 5, 3 had epithelioma of the tongue, jaw, or larynx, and thus the changes were probably largely due to inhalation pneumonia. 1 followed nephrorrhaphy. 1 followed amputation of an arm.

Thus, of 18,639 operations only 26 showed acid digestion of the lungs; of these 21 had general peritonitis and only 2 are left in whom the condition might possibly have been due to anæsthetic vomiting. But when we examine the 21 cases without operation we find:—General peritonitis present in 7; gastric ulcer (causing death) in 1 (vomiting of peritoneal origin); septicæmia in 4; perforation of cancer of the œsophagus to the lung in 2; burns in 4 (probably early post-mortem or septic changes); diabetes in 1; accident in 1; pneumonia in 1 (cause unknown). Thus, in this series we find an even larger percentage with acid digestion from no known cause which could not have been the administration of an anæsthetic, as none was given; and therefore it is probable that this unknown cause in the first series might have been some factor other than the anæsthetic.

Of course, food should not be given so shortly before an operation that gastric distension is caused. In this hospital the more rational course is now pursued; the patient is encouraged to take as large a breakfast as possible eight hours before operation, a cup of beef-tea is then given about five hours, and a second about three hours before operation. The only objection that can be raised against this course is the stimulant properties of the beef-tea; it might probably be better replaced by some light fluid diet.

The anæsthetic must be carefully chosen and in all cases where possible ether should be administered, or if chloroform be given this should be in mixture with ether. Should there be any marked counter-indication to the use of ether spinal anæsthesia would, from the point of view of shock alone, be indicated in preference to chloroform.

In the direct prevention of the fall of blood pressure many methods may be adopted. Undoubtedly the best of these is the pneumatic suit introduced by Crile. It consists of a rubber suit which is applied to the body and limbs, the pressure within being raised and maintained at any level by means of a hand pump. If, at the same time, blood pressure tracings are taken and recorded at short intervals, the pressure may be kept absolutely under control. As Crile points out, its use is specially adapted for operations upon the head; as has been pointed out, these operations are often associated with marked shock, which is accentuated by the accompanying and often severe loss of blood. By the application of the suit the shock may be prevented, and by sitting the patient up the bleeding can be greatly diminished, the steps in the operation being thus made clearer and the difficulties lessened.

Since the condition of shock is chiefly due to the accumulation of blood within the splanchnic area, this method cannot be so satisfactorily used in acute abdominal cases. In these, however, some good may be accomplished by applying such a suit to the limbs, or having these tightly bandaged previous to operation. Crile's experiment, showing that abdominal operations were free from shock when the superior mesenteric artery had been previously clamped, suggests that some means of temporary ligature might, in these cases, be adopted. The method of such temporary ligature in the case of the common carotid artery was, I believe, first introduced by Mr. Rivington,[6] of this hospital, and several other cases were dealt with in a similar manner by Sir Frederick Treves.[7] In one case the temporary ligature was applied for half an hour with no subsequent complication. Crile has invented a rubber-coated clamp which he has applied to the common carotid, and states that in dogs it may be kept in position for as long as 24 hours without damage to the artery. Hence it is possible that a similar clamp might be used for a short period on the superior mesenteric artery, but further experiments, showing how long the gut might safely be left without its blood-supply, are necessary before such a method is brought into practice.

The fact that exhaustion of the vaso-motor centres is caused by afferent impulses passing along the main nerve trunks suggests that any method which will prevent the passage of these impulses will be of value in preventing shock. Crile adopted the method of injecting cocaine into the main nerve trunks in his experiments, and no shock resulted, however severe the injuries. Lockhart Mummery and Cushing have also used this method in man previous to large amputations, such as the fore-quarter, and found that there was no fall of pressure on dividing the nerves, but in cases of a similar nature where this previous treatment was not adopted there was a marked fall. This method being very simple and having a marked effect deserves a far wider application in all cases of amputation of a limb. A 2 to 4 per cent. solution of cocaine should be used; at the same time trauma to any area richly supplied with nerves should be limited as far as possible. This is specially so in the case of abdominal operations; here mere exposure of the intestines is sufficient trauma to cause a marked effect, although it is perhaps aided by evaporation from the exposed peritoneal surfaces. Hence evisceration should be avoided as far as possible, and if it be found necessary to turn out the intestines they must be protected by sterile towels wrung out in hot saline solution.

The next question that has to be considered is the maintenance of the bodily heat. This should be kept as near normal as possible, as it is found that shock is always associated with a fall of temperature, and it seems highly probable that this may be a causative factor. It may, however, easily be overdone, and if the patient be made to sweat freely there is no doubt that the excessive dilatation of the capillaries will largely aid in keeping down the already lowered pressure; at the same time the free loss of fluid by evaporation will tend to keep up the concentration and high specific gravity of the blood, which has been shown to be constantly present in this condition.

(b) *Curative.*

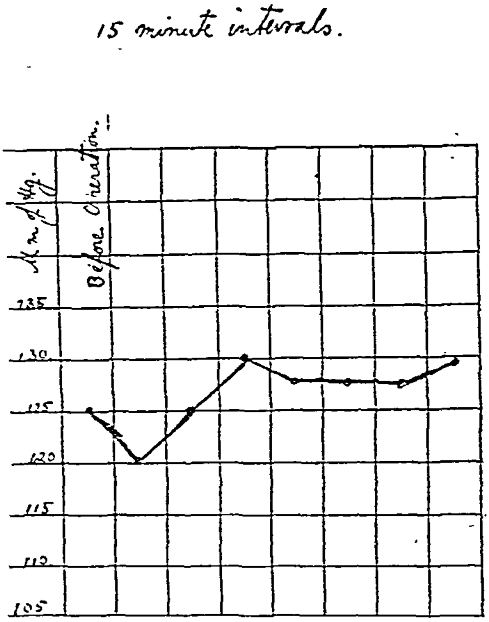
The curative methods to be made use of when once the condition has been established will have to be considered under the following headings: Drugs, Infusion of fluids, and Mechanical methods.

Drugs.—It is in this direction that general improvement in the lines of treatment is most necessary. In a large number of cases the condition of shock is largely treated by dosing the patient with strychnine and by administering coffee and brandy either by the mouth or as enemata. As will be shown, such treatment appears to be not only useless but positively dangerous, and one is often struck by their marked failure in severe cases to cause any reaction whatever; in fact, the patient tends to go steadily down hill.

The effect of various drugs in this condition is as follows:—

Strychnine.—In health this has been shown to have a very marked effect upon the blood pressure; the vaso-motor centres are stimulated, the peripheral vessels thereupon contract, and this is followed by a marked rise in the pressure. A similar change occurs with very slight degrees of shock. But in the more severe degrees, since the whole condition is due to an exhaustion of these centres, one would not expect that their stimulation would be followed by any valuable result; in fact, a further exhaustion would be expected. As already mentioned, Lockhart Mummery[1] and Crile[2] have shown that in profound shock in animals there is no rise in pressure after the administration of strychnine and the former has also shown that in the same condition in man there is no rise. In very slight cases, then—i.e., those that really require no drug treatment—there is a reaction to the drug, as is shown in Fig. 4. This chart, together with the five following, I have been able to obtain by the aid of one of the sisters here and by the courtesy of Dr. G. F. Bird and Dr. R. S. Woods. In this case the pressure never fell more than five millimetres of mercury below the normal and therefore never presented symptoms. In slightly more severe cases there is a preliminary rise, but this is soon followed by a more marked fall, the subsequent height of the pressure being less than that before the administration of the drug. Such a condition is well shown in Fig. 5. In severe cases of shock this preliminary rise is absent also and the use of strychnine with stimulants is followed by a steady fall in pressure. It has been suggested that these effects are due to the fact that absorption does not take place owing to the lowered pressure; that this is not so is shown by the fact there is no rise even if the drug be injected intravenously. The same ill-effects are likely to occur with preliminary injections of strychnine as a preventive measure; one dose of 1-60th or 1-30th of a grain given immediately beforehand is only likely to lead to an exhaustion of the centres and thus render them less able to resist the causes of shock. Lockhart Mummery has, however, suggested that the drug might in certain cases be given regularly for about a week before operation in the hope of causing physiological hypertrophy of the centres. Figs 6 and 7 are from cases of severe shock treated with strychnine; the contrast with Fig. 4 is striking; not only is there no reaction but a steady fall occurs.

FIG. 4.

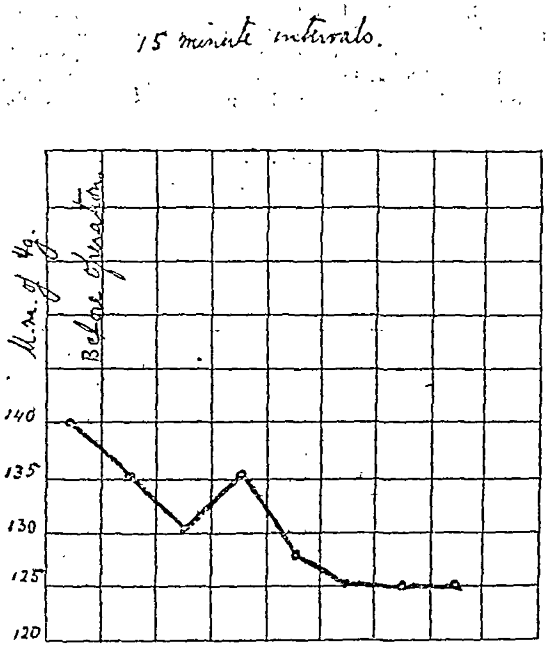


Patient aged 11 years. Fæcal fistula. Lateral anastomosis. The patient was given strychnine, 1-60th of a grain, and a second 1-60th a quarter of an hour later in the theatre. On returning to the ward one ounce of brandy was given. The very slight amount of shock and the ready reaction to stimulants are seen.

Other stimulants.—An effect similar to that caused by strychnine follows the use of other stimulants, as shown both by experiments upon animals and by clinical observations.

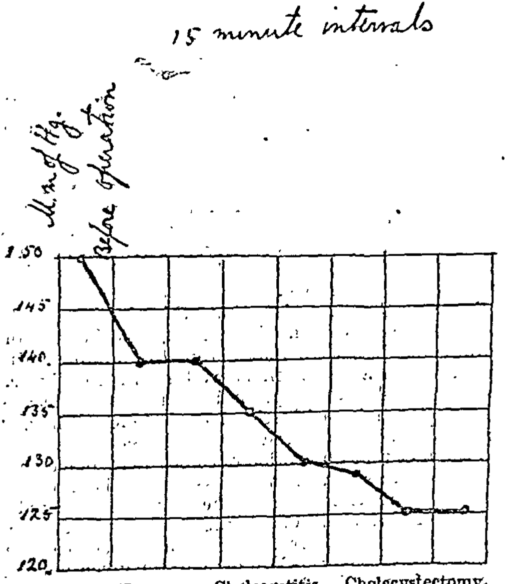
With ether and brandy the harmful effects are more marked, for these drugs cause a dilatation of the peripheral vessels. Thus it may be stated that these drugs should not be given in cases of moderate or severe shock as they are only liable to increase the fall in pressure and that their use previous to or during operation is to be condemned on the same grounds.

FIG. 5.



Patient aged 53 years. Obstructed umbilical hernia. Moderate shock. 1-30th of a grain of strychnine and four ounces of brandy were given. The slight rise of pressure followed by a more marked fall is well seen.

FIG. 6.



Patient aged 45 years. Cholecystitis. Cholecystectomy. *Severe shock.* 1-30th of a grain of strychnine was given. There is a steady fall of pressure from the commencement. Two pints of saline solution were also given per rectum.

Atropine acts in somewhat similar manner, causing a preliminary stimulation followed by paralysis of the vaso-motor centres.

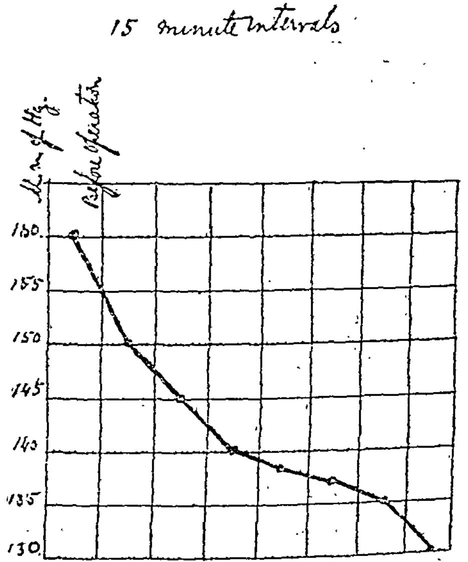
Cardiac stimulants.—Good examples of these are digitalis and strophanthus; they act by stimulating the heart itself and thus affect the other factor concerned in the maintenance of the pressure. But, as previously shown, in cases of severe shock, the rapidity of the heart has already increased as far as possible but has failed to overcome the fall, hence but little good is likely to follow the use of such drugs, and clinically such is found to be the case.

The next series of drugs to be considered has a completely different action, the exhausted centres are left untouched and allowed to recover naturally, but the vessels themselves are directly stimulated to contract, and as they are not exhausted this would be expected to be followed by a marked reaction with a rise in pressure.

Suprarenal extract.—Of the drugs at present in use this has the most evident effect upon the blood pressure and causes a considerable rise. Its action in causing contraction of the peripheral arterioles is now well known. Mummery and Crile have shown that its injection in cases of severe shock is followed by a very characteristic rise in pressure, and in the case of the pithed animal, previously mentioned, Crile found that strychnine had no effect, but the injection of suprarenal extract caused the pressure to rise again to the level of normal. If given by the mouth its composition seems to be altered so that no effect follows.

It is stated that when given subcutaneously there is no absorption owing to the local contraction of the vessels, but in a case of elevation of a depressed fracture of the skull and removal of a large area of bone this method used continuously was followed by a marked improvement. The pulse immediately after operation could not be felt at the wrist, but a quarter of an hour after injection had been commenced it was nearly as strong as normal and the patient made a perfect recovery. I regret that in this case no tracing was taken. It is probable then that some absorption does take place, but it is liable to be followed by some local necrosis and therefore this method should not by preference be used. In the same way it is stated that if given by the rectum either it is not absorbed or is altered in composition before absorption. But in many cases where the patient has been treated by this method a well-marked reaction has been shown by tracings (Figs. 8 and 9). It may be claimed that the whole effect in these cases is due to the fluid absorbed at the same time, but in other cases (Figs. 6 and 7) where fluid was given with no suprarenal extract the effect was either absent or not so marked. So from these observations it would seem to be a useful method of administering the drug, and, for reasons which will be mentioned later, is the method to be adopted for preference. It is usually given by continued intravenous injection, but this presents some practical difficulty. A similar effect follows the use of hemisine.

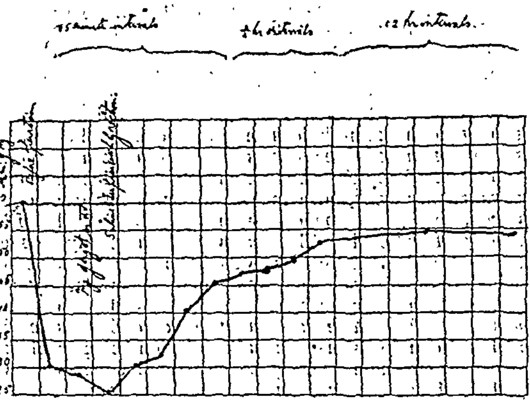
FIG. 7.



Patient aged 56 years. Gastric ulcer. Anterior gastrojejunostomy. *Severe shock.* Patient was given 1-30th of a grain of strychnine and one ounce of brandy. There is a steady fall of pressure from the commencement. Two pints of saline solution were also given per rectum.

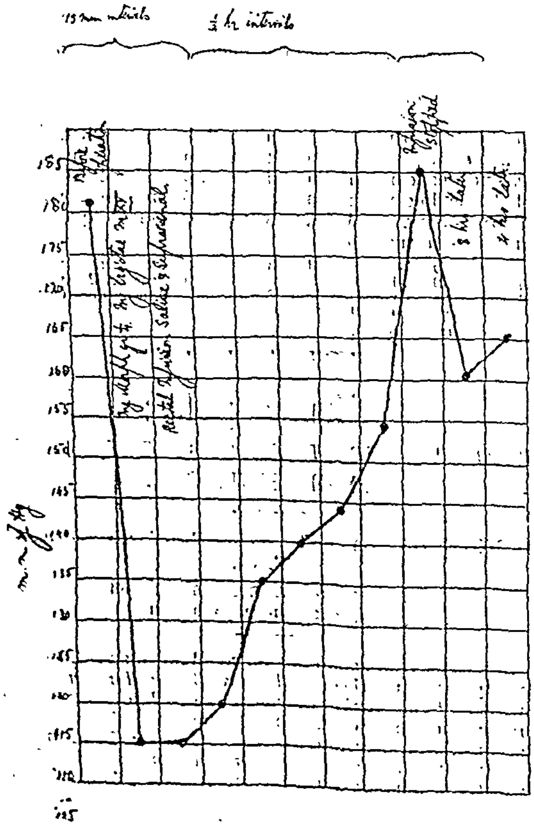
The objection to the use of these derivatives of the suprarenal gland is that their effect lasts only for a few minutes, three or four; this is, however, readily overcome by continuous injection, which may be made to last some hours, and thus the effects of the drug maintained until the condition of shock has passed off, and as it produces its effects even when given in small doses, sufficient is not administered even by these continuous methods to give rise to any toxic symptoms. Crile advises that it should be given in a 1-50000 or 1-100000 solution. The strength I prefer is 1-160000, that is one drachm to the pint of the solution sold. This is a dilution easy to remember and to make up, and appears to be sufficiently strong for its purpose. The dilution is made with normal saline solution.

FIG. 8.



Patient aged 25 years. Strangulation of gut by diverticulum. *Severe shock.* Patient was given ergot hypodermically and continuous rectal infusions of saline solution and suprarenal extract 1-160000th Oi. per hour, also injections of morphine ¼ grain. The rise in pressure after the suprarenal is well marked.

FIG. 9.



Patient aged 52 years. Amputation of breast, removal of axillary glands. *Severe shock.* Patient was given ergot hypodermically, and continuous rectal infusion of saline solution and suprarenal extract 1-160000th Oi. per hour, also injections of morphine ¼ grain. The marked fall in pressure from the operation, and the steady rise, even to above normal, are well shown.

As regards the method of administration, intravenously is perhaps the best physiologically, but it necessitates the formation of a new wound with after-pain to the patient, and it is more difficult to manage. When the fluid is given for some hours it must be left in charge of a nurse, to whom the methods of dealing with blockage of the tubes, leakage, &c., often present considerable difficulties. Subcutaneous injection has the same objections, with the addition that the insertion of a large quantity of fluid here, even if given slowly, may cause considerable pain, and, if the solution be too strong, may even cause sloughing of the overlying skin. In one case where the solution was given 1-20000, an area about six inches by four inches sloughed out of the inner side of each thigh, and necessitated subsequent skin grafting. Continuous rectal injection presents none of these difficulties. A rubber tube is arranged as a syphon from the bowl of fluid, which is raised about one foot above the level of the patient. At the other end of the tube is connected a glass vaginal nozzle, which is passed three or four inches up the rectum, and the fluid, at a temperature of from 108° to 112°F., is allowed to run in at the rate of one pint an hour. The only objection that can be raised is that the absorption of the extract does not take place, but I have already shown that this objection does not seem to hold good.

Ergot.—The effects of this drug are very similar to those of the suprarenal products, but they last considerably longer. Lockhart Mummery,[1] experimenting with it upon a cat, showed that a steady rise was caused which was maintained for 20 minutes. The objections to it are that its preparations are uncertain; a useful and fairly reliable one is the B.P. hypodermic injections, as made at the dispensary of this hospital—15 minims will be found a useful dose.

Morphine.—As already mentioned, the anæsthetic, by decreasing the pain and the afferent impulses to the vaso-motor centres, decreases the amount of shock. As the effect of the anæsthetic passes off and the pain of the wound becomes again appreciable it would be expected that the shock would be more marked, and such is often found to be the case; Figs. 5, 6, and 7 show a steady fall of pressure after the operation has ceased. By giving morphine this appreciation of pain is much decreased and the condition of shock is not maintained; morphine is also well known as a cardiac stimulant and is thus of use for this effect.

(To be concluded.)

EXTIRPATION OF THE LACRYMAL SAC.

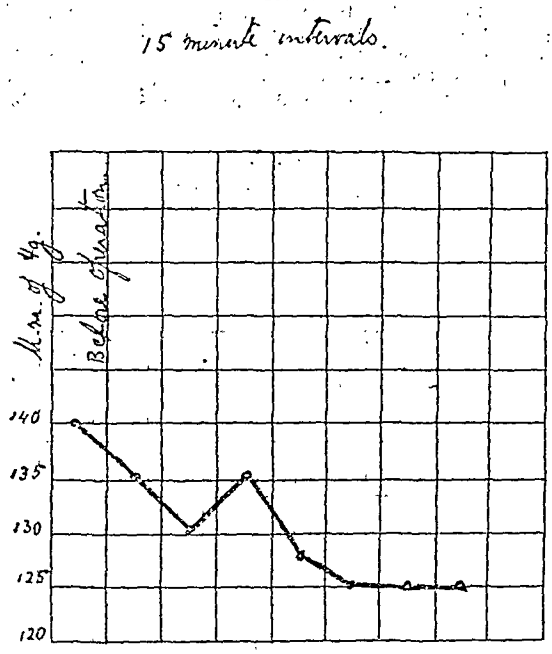
BY O. J. CURRIE, M.B. LOND. & CAPE UNIV.,
M.R.C.S. ENG.,
SURGEON TO GREY'S HOSPITAL, PIETERMARITZBURG.

THE lacrymal sac is deeply situated at the lower and anterior part of the inner wall of the orbit, resting on the lacrymal groove. It forms the upper dilated end of the lacrymo-nasal duct, which drains the conjunctival sac and conducts superfluous tears into the nasal cavity.

Dacryocystitis, or inflammation of the lacrymal sac, may be acute or chronic. Acute cases should be treated with hot fomentations, pus should be evacuated if an abscess forms, and the sac should be syringed out through the incision or through the upper or lower canaliculus. Probing the nasal duct should not be resorted to until after syringing out the sac has been given a trial, and not in any case until the acute symptoms have subsided. Chronic dacryocystitis should be treated as follows. First, by syringing out the sac with antiseptic and astringent lotions, such as solutions of boric acid, chinosol, or argyrol; secondly, if perseverance in the above treatment fails, by slitting the upper or lower canaliculus and dilating the nasal duct with probes; and thirdly, in neglected or intractable cases which cannot be cured by the above means, destruction or extirpation of the lacrymal sac is necessary.

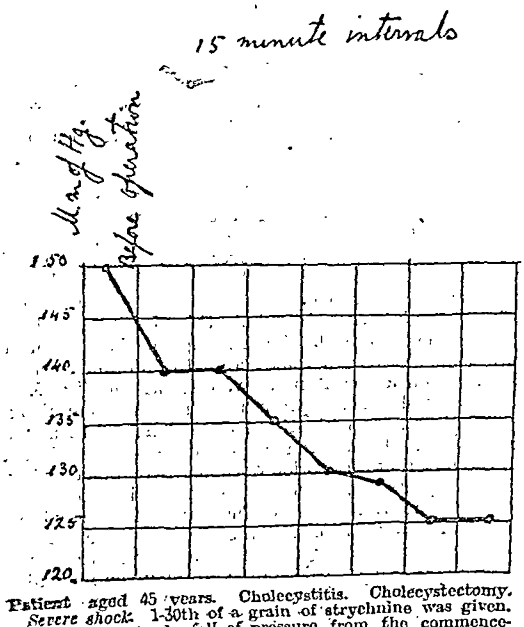
With ether and brandy the harmful effects are more marked, for these drugs cause a dilatation of the peripheral vessels. Thus it may be stated that these drugs should not be given in cases of moderate or severe shock as they are only liable to increase the fall in pressure and that their use previous to or during operation is to be condemned on the same grounds.

FIG. 5.



Patient aged 53 years. Obstructed umbilical hernia. Moderate shock. 1-30th of a grain of strychnine and four ounces of brandy were given. The slight rise of pressure followed by a more marked fall is well seen.

FIG. 6.



Patient aged 45 years. Cholecystitis. Cholecystectomy. *Severe shock.* 1-30th of a grain of strychnine was given. There is a steady fall of pressure from the commencement. Two pints of saline solution were also given per rectum.

Atropine acts in somewhat similar manner, causing a preliminary stimulation followed by paralysis of the vaso-motor centres.

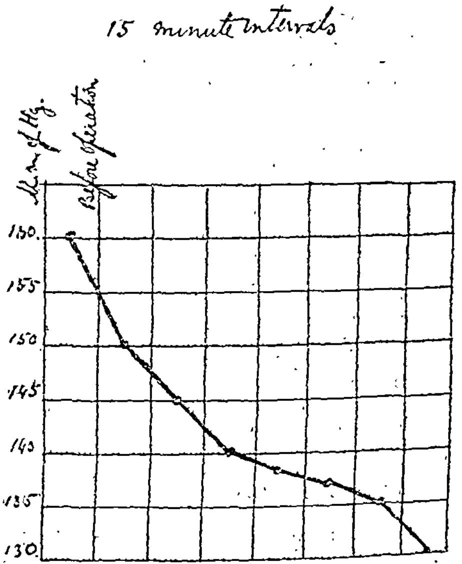
Cardiac stimulants.—Good examples of these are digitalis and strophanthus; they act by stimulating the heart itself and thus affect the other factor concerned in the maintenance of the pressure. But, as previously shown, in cases of severe shock, the rapidity of the heart has already increased as far as possible but has failed to overcome the fall, hence but little good is likely to follow the use of such drugs, and clinically such is found to be the case.

The next series of drugs to be considered has a completely different action, the exhausted centres are left untouched and allowed to recover naturally, but the vessels themselves are directly stimulated to contract, and as they are not exhausted this would be expected to be followed by a marked reaction with a rise in pressure.

Suprarenal extract.—Of the drugs at present in use this has the most evident effect upon the blood pressure and causes a considerable rise. Its action in causing contraction of the peripheral arterioles is now well known. Mummery and Crile have shown that its injection in cases of severe shock is followed by a very characteristic rise in pressure, and in the case of the pithed animal, previously mentioned, Crile found that strychnine had no effect, but the injection of suprarenal extract caused the pressure to rise again to the level of normal. If given by the mouth its composition seems to be altered so that no effect follows.

It is stated that when given subcutaneously there is no absorption owing to the local contraction of the vessels, but in a case of elevation of a depressed fracture of the skull and removal of a large area of bone this method used continuously was followed by a marked improvement. The pulse immediately after operation could not be felt at the wrist, but a quarter of an hour after injection had been commenced it was nearly as strong as normal and the patient made a perfect recovery. I regret that in this case no tracing was taken. It is probable then that some absorption does take place, but it is liable to be followed by some local necrosis and therefore this method should not by preference be used. In the same way it is stated that if given by the rectum either it is not absorbed or is altered in composition before absorption. But in many cases where the patient has been treated by this method a well-marked reaction has been shown by tracings (Figs. 8 and 9). It may be claimed that the whole effect in these cases is due to the fluid absorbed at the same time, but in other cases (Figs. 6 and 7) where fluid was given with no suprarenal extract the effect was either absent or not so marked. So from these observations it would seem to be a useful method of administering the drug, and, for reasons which will be mentioned later, is the method to be adopted for preference. It is usually given by continued intravenous injection, but this presents some practical difficulty. A similar effect follows the use of hemisine.

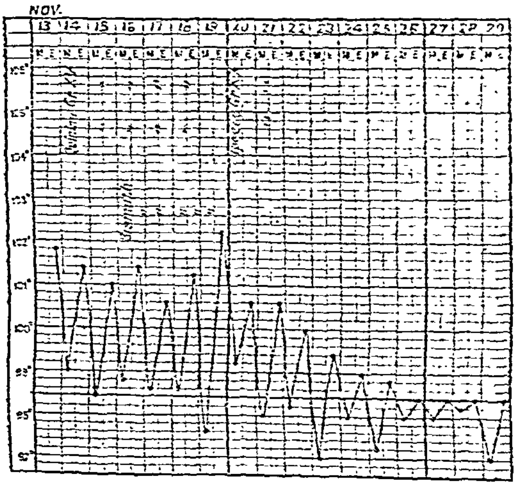
FIG. 7.



Patient aged 56 years. Gastric ulcer. Anterior gastro-jejunostomy. *Severe shock.* Patient was given 1-30th of a grain of strychnine and one ounce of brandy. There is a steady fall of pressure from the commencement. Two pints of saline solution were also given per rectum.

ten days of his illness; afterwards Dover's powders and a diet of goat's milk. He had had no nausea, vomiting, cough, or symptoms referable to the chest or abdomen; the stools, two or three per diem, had been "porridgy"; there was no blood, mucus, or pain with movements of the bowels. His previous history elicited an eight months' residence in this country during which he had had many attacks of "fever"; one attack had been thought to be tick-fever; in the last attack, however, malarial parasites had been found. Previous to coming to this country he had been in South Africa for nine or ten years, and in 1901 had been treated in Bloemfontein Hospital for enteric fever, followed one week after discharge by dysentery with typical acute symptoms, the attack lasting four weeks. Since then, till the present illness, he had had no returns of symptoms or diarrhœa.

On the evening of admission the blood was examined for malarial parasites and two only were seen, ring forms (malignant tertian), no crescents. The following five days quinine was given: 15 grains the first two days and then 20 grains as solution of bi-hydrochlorate. This had no effect on the temperature, which showed an evening rise, averaging 101°, and the pulse was from 66 to 88 per minute. The urine was normal. There were two motions per diem, watery, with little fæcal matter, but neither mucus nor blood except on the second day after admission when what appeared to be a small old blod clot was passed. No improvement was effected by 20-grain doses of bismuth three times a day for three days. Microscopical examination of the stools proved negative as regards amœbæ. The tongue was thickly furred and the patient complained of weakness, headache, and profuse sweats in the evening. The spleen could just be felt; the liver showed no enlargement to percussion or tenderness to palpation; there were no other physical signs in the chest or abdomen. At the end of the week, during which time no other malarial parasites had been found, quinine was discontinued and it was determined to try ipecacuanha. It was given in wafer, in 20-grain doses, on two consecutive days on an empty stomach, 20 minutes after a 20-minim dose of tincture of opium, as recommended by Manson. The result was immediate: the temperature commenced to fall, reaching normal in four days, and thereafter not rising again; the stools became more and more formed, being normal in three days; the tongue cleaned, and the patient expressed himself as feeling much better. The convalescence was uneventful, full diet being attained by the end of a week of normal temperature.



The complete chart also recorded a pulse frequency varying from 66 to 90, generally keeping between 80 and 88. The record of the evacuations showed "2 loose" on the second day, "3 loose" on the third day, then "2 loose" with one intermission until the twelfth day, after which "1 formed" is recorded daily with two intermissions. The diet is also described. "Nov. 13th: Milk, soda, chicken broth. Nov. 25th: Milk pudding, bread and butter. Nov. 28th: Eggs, toast, fish, potato. Dec. 1st: Chicken, duck."

Major Rogers lays stress on a particular type of leucocytosis as being of value in making a diagnosis in these cases. Unfortunately, I was unable to make a "white count" till after the treatment had done its work—white cells then numbered 9000 per cubic millimetre. I think, however, that with the past history of dysentery the three weeks' pyrexia, immediately reacting to treatment by ipecacuanha, places this case among those that Major Rogers puts in Class IV. of his series, "Cases without Dysentery or Liver Symptoms treated with Ipecacuanha."

Blantyre, Nyasaland.

A NOTE ON THE EXTRACTION OF FOREIGN BODIES FROM THE TISSUES.

BY HUBERT CHITTY, M.S. LOND., F.R.C.S. ENG.,

RESIDENT CASUALTY HOUSE SURGEON, ST. MARY'S HOSPITAL, PADDINGTON.

THE following description applies only to the removal of those bodies which are opaque to the x rays. The patient is taken into the x ray room and the foreign body is roughly localised with the aid of a fluorescent screen. The area in which an incision will have to be made is then carefully cleansed and is infiltrated with a 1 per cent. solution of eucaine. A further examination of the part is now made with the x rays. Guided by the shadows thrown upon the screen, the surgeon plunges the needle of the infiltrating syringe into the tissues till it touches and (in the case of a needle) lies as nearly as possible parallel to the foreign body. A few more drops of solution may now be injected and the syringe is then detached from its needle, which is left sticking into the part. This needle is cut down upon and the incision necessarily exposes the foreign body at the same time.

Except where the foreign body lies very deeply it is often quicker to surround both it and the localising needle by an elliptical incision and to remove them both, together with a little skin and subjacent tissue, in one mass. The wound when closed by a stitch or two leaves no more scarring than does a linear incision.

I have chiefly used this method in cases of "needle in the hand," but it is, of course, equally applicable to the removal of glass, shot, &c. It is rapid and certain, and the minimum of damage is inflicted on the soft parts. Strict asepsis is easily maintained, for, once the infiltrating needle has been brought into contact with the foreign body, no further screening of the part is required.

This plan for localising a foreign body is simpler and more accurate than any method of skin marking with which I am acquainted. Anyone who has had to hunt for small pieces of needle deeply imbedded in the muscles will appreciate its advantages.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

The Tone of Cardiac Muscle.

A MEETING of this section was held on June 23rd, Dr. D. B. LEES being in the chair.

Dr. A. M. GOSSAGE read a paper on the Tone of Cardiac Muscle. He said that muscle was probably capable of two kinds of contraction—the ordinary twitch and "tone," and these might occur separately or in combination. Tone was never absent, so that the ordinary muscular contraction was superimposed on tone, but increase of tone diminished the size of that contraction; in other words, tone diminished contractility. Tone, unlike the ordinary muscle twitch, had no refractory period and was directly dependent on the strength of the stimulus. Tetanus was purely a phenomenon of tone. In cardiac muscle Porter had shown that tone diminished conductivity as well as contractility and it was probable that it also diminished excitability. Dilatation of the heart was due to loss of muscular tone and, as would be expected, was associated with increase of excitability, conductivity, and contractility.

Theobald mentions the following surgical procedures for the cure of dacryocystitis: (1) The restoration of the natural passages; (2) the formation of a new passage into the nose; (3) the obliteration of the natural passages, the lacrymal sac and duct; and (4) the removal of the lacrymal gland. Desmarres recommended the third of these proceedings only when the case was incurable by other means. Theobald agrees with this and recommends the use of large-sized probes as a means of restoring the patency of the nasal duct.

H. Knapp gives the following indications for extirpations of the lacrymal sac, viz.:—In all cases where an important lacrymal disease can otherwise not so well or not at all be cured, as in the following conditions: (1) Large mucocele; (2) chronic lacrymal fistula; (3) fibrous or osseous occlusion of the nasal duct with lacrymation and discharge; (4) chronic stricture of the nasal duct with lacrymation and discharge; (5) chronic dacryocystoblennorrhœa with degeneration of the walls of the sac; and (6) chronic catarrhal dacryocystitis with repeated attacks of phlegmonous inflammation.

Although destruction of the lacrymal sac by the actual cautery in cases of lacrymal fistula appears to have been performed in the days of Celsus it was not till 1724 that the more surgical procedure of extirpation by the knife was performed by Platner, and there still seems to be some divergence of opinion among surgeons as to the indications for the operation and also as to whether the knife or the cautery should be employed. I think it is now generally recognised that the operation might be more frequently performed than it is in cases of dacryocystitis, which, owing to neglect of the patient or perhaps unwise or too vigorous treatment in the early stages, have lapsed into a state of chronic suppuration. The old treatment by caustics or the cautery is now being rejected in favour of the cleaner and more surgical proceeding of extirpation.

The objections urged against the operation are its dangers and difficulties. The chief danger is orbital cellulitis and its complications, which can be avoided by careful asepsis and by drainage of the wound. The sac must be frequently syringed out with an antiseptic lotion for some days before the operation in order to diminish the risk of infection of the wound, and drainage by means of a few strands of catgut or a fine strip of gauze should certainly be employed in order to give exit to any blood or serum which might form a nidus for the growth of pathogenic germs in the depths of the wound.

The difficulties of the operation arise from the deep situation of the sac beneath the tendo oculi and from the field of view being obscured by hæmorrhage. The former can be readily overcome by making the incision sufficiently free and by the use of suitable retractors, such as Axenfeld's, and the latter is now avoided by sponging out the wound with adrenalin solution (1 in 1000).

It is a curious fact that complete removal of the lacrymal sac results in a cure of the epiphora. There are two theories to account for this apparent paradox. 1. Physiological sympathy induces the gland to cease secreting. 2. That under normal conditions the amount of tears secreted by the gland is only sufficient to keep the conjunctiva moist and that in health, unless under exceptional circumstances, such as emotion or irritation of the conjunctiva, there is no excess of tears and no overflow down the nasal duct. Probably both these hypotheses are correct, as it is stated that if a portion of the lacrymal sac is accidentally left behind it excites a reflex secretion of tears and keeps up watering of the eye. The following case, which has recently been under my care, illustrates many of these points.

A boy, aged 13 years, was kicked in the face by a horse about six years ago. The result of this accident was the formation of a lacrymal abscess and fistula. About a year after the accident he came under my care suffering from chronic dacryocystitis and lacrymal fistula. The treatment adopted consisted of first syringing out the sac; afterwards the lower canaliculus was slit and the nasal duct was probed. The edges of the fistula were curetted and on the establishment of drainage into the nose the fistula healed. The sac, however, continued to secrete pus, but the patient, refusing further treatment, ceased to attend and did not come under my care again till December, 1907. When I saw him then the lacrymal sac was secreting pus freely, the upper lid was covered with velvety granulations, the conjunctiva was intensely injected, and the cornea was inflamed, vessels beginning to extend into its substance, forming pannus. Great photophobia and lacrymation were prominent symptoms. Conjunctivitis and keratitis were also present in the other eye. The conjunctiva was washed many times daily with boric acid lotion, and the lacrymal sac was syringed out with chinosol solution 1 in 4000. This treatment was only kept up for a few days, as the boy again became impatient, and on Jan. 2nd the operation of excision of the lacrymal sac was performed. The mucous membrane along the upper edge of the tarsal cartilage of the upper lid was first excised with scissors in order to diminish the vascular supply to the granulations on the eyelid. The usual antiseptic precautions were observed and chloroform having been administered an incision about one and a half inches in length, commencing well above the tendo oculi, was carried downwards, and then round the inner third of the inferior margin of the orbit. The sac, which was easily recognised by its bluish-white colour, was cleared; the tendo oculi being divided, the sac was then separated from the bone beneath by means of the knife and curved scissors. The whole sac was then carefully dissected out with knife and scissors; adrenalin solution being employed to arrest hæmorrhage. Owing to cicatricial adhesions a small portion of the sac was torn off and left behind; this was afterwards dissected away and the wound was freely curetted. The canaliculi were cut through and the nasal duct, as far as possible, separated with fine scissors and knife from the lacrymal canal, and the upper part of the nasal duct divided. The wound was stitched up with fine silk, including the skin and tendo oculi with its fibrous expansion, and a small gauze drain left in the lower angle. As the eyelids were swollen and puffy for a day or two after the operation the gauze drain was kept in for three or four days. There was a certain amount of suppuration in the track of the drain but the temperature never rose above 99° F. and in about a fortnight the wound was soundly healed. The inflammation of the conjunctivæ and corneæ gradually subsided, and when last seen, excepting for the slight scar, the eye had quite its normal appearance. There was no weakening of the lids in consequence of the division of the tendo oculi, the latter having been carefully stitched. There was no epiphora, except when caused by emotion or any unusual irritation.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON LATENT DYSENTERY IN CENTRAL AFRICA.

By HUGH S. STANNUS, M.B. LOND.,
MEDICAL OFFICER, NYASALAND.

IN a paper read before the Royal Medical and Chirurgical Society, and published in the *Practitioner* for June, 1907, entitled "The Early Diagnosis and Cure of the Pre-suppurative Stage of Amœbic Hepatitis," Major Leonard Rogers, I.M.S., described a series of cases in India presenting symptoms which he has shown are associated with the hepatitis of amœbic dysentery before abscess formation and which are capable of cure by ipecacuanha. It is with the idea of drawing the attention of those practising in Africa to the fact that this class of case may be met with in this continent that I give a short account of a case occurring in Nyasaland.

A man, single, aged 30 years, was admitted to hospital on Nov. 13th, 1907, with a temperature of 101·8° F. and a pulse-rate of 80. He was depressed, weak, and unable to walk. He gave a history of two weeks' fever, headache, malaise, with some looseness of the bowels. He had taken 20 grains of quinine per diem during the first became irregular under the administration of digitalis. That irregularity was of several kinds, of which the commonest form was the development of a "bigeminal action" where an extra-systole followed each normal beat. A bigeminal action was not uncommon in over-excitable hearts where no drug had been employed, and a probable explanation of its occurrence after digitalis was that the decreased rate had allowed a hidden bigeminal action to appear. For that explanation to be applicable it was necessary that the interval before the extra-systole should be longer than the intervals between adjacent beats before the administration of digitalis. Hering showed that a bigeminal action might be made to disappear by giving atropine, its disappearance coinciding with the time when the normal rhythm became so rapid that a normal beat occurred exactly at the moment when the extra-systole would be expected: any rate faster than that was regular, while any slower rate, as shown when the effect of the atropine wore off, was of the bigeminal character. A bigeminal action was not necessarily constant and they would not always expect a constant bigeminal action in cases occurring after digitalis. It was not necessary, therefore, to assume that in these cases the digitalis caused an increase of excitability contrary to its usual action of decreasing excitability. A second type of irregularity after digitalis might be produced by the occurrence of isolated extra-systoles. That might, of course, be merely a consequence of reduction of rate, since with a rapid rhythm there was very little opportunity for the occurrence of extra-systoles. Another type of irregularity after digitalis had to do with the depression of quite a different property of the muscle—namely, conductivity. There was abundance of evidence that digitalis depressed conductivity in animals and Mackenzie had shown that the same action took place in human beings provided that conductivity was somewhat depressed before the drug was given. In some cases there might be an apparent improvement in conductivity after digitalis owing to the slower rate giving more time for its recovery. In view of the small doses that it was possible to administer it is not surprising that depression of conductivity by digitalis was only observed clinically in cases where there was already evidence of its being damaged. The effect of digitalis on contractility was more difficult to estimate. There was no doubt of the more efficient working of the heart when digitalis had been given in suitable cases. That was partly due to the mechanical advantage of the decreased dilatation brought about by increased tone and partly due to the fact that the slower rate allows a longer time for the contractility to recover. In animal experiments, however, it was clear that both an increase of tone and the administration of digitalis resulted in a diminution of contractility. That drug, too, often produced an alternating action of the heart which had been supposed to be the expression of damaged contractility. The evidence of depression of contractility by digitalis in the human heart seemed sufficiently clear and they could have no doubt of that action of digitalis from the results of animal experiments. Probably only those patients whose contractility was already depressed would show any further recognisable lowering with digitalis. The foregoing arguments afforded sufficient justification for affirming that tone played the same important rôle in the human heart as in the animal and that increase of tone had the effect of diminishing the other properties of the cardiac muscle—namely, contractility, excitability, and conductivity. That conclusion, too, was of considerable clinical importance. The recognition of loss of tone as the important factor in dilatation of the heart was a great advance, and they now found in addition that many of the phenomena associated with dilatation were directly due to that loss of tone. The dependence of the other properties on tone afforded a remarkable method of self-regulation in the heart, so that it was enabled to do just the amount of work which was required of it. Some light was also thrown on the obscure subject of the action of digitalis on the heart, though it could not be said that that question was completely answered. Part of the action of digitalis was evidently secondary to its influence on the muscle tone, but how much of the damage done to contractility, conductivity, and excitability came from increased tone and how much from stimulation of the vagus could not at present be estimated. The narrowing of the coronary vessels would probably also tend to depress the properties of the cardiac muscle to an extent that was incapable of exact appreciation. It was important to note that in the case cited the digitalis had greatly improved the patient's general condition as well as the general working of the circulation in spite of the grave depression of conductivity and the occasional dropping out of ventricular beats. Mackenzie's and Gibson's patients had also benefited from the drug, although contractility was so damaged that there was alternating action of the heart. Evidently the improvement resulted from the increase of tone and these facts received their simplest explanation in the conception of tone that he (Dr. Gossage) had advanced.

Dr. J. MACKENZIE said that the paper had helped him to understand why there was an increase in the rate of the heart's beat in cases where sudden dilatation had taken place.

Professor A. R. CUSHNY said that it was interesting to find Dr. Gossage going back to the view that the action of digitalis on the heart may be due to what was called its elasticity, which was very much the same thing as the tonicity described by Dr. Gossage.

Dr. A. MORISON said that in the discussion of the subject they could not eliminate the influence of the nervous system or that of the blood.

Dr. H. A. CALEY said that the value of the paper by Dr. Gossage consisted in the evidence which it contained that digitalis was indicated in cases of cardiac myasthenia with dilatation, and if digitalis failed to do good in such circumstances causes such as degeneration of the coronary arteries or actual degenerative changes in the myocardium itself must be considered.

Dr. LEES laid stress upon the importance of ascertaining the true size of the heart in cardiac conditions which he said could quite easily be done by careful percussion. The use of digitalis was not indicated in cases of dilated heart due to an acute toxic condition, but where the condition was chronic then digitalis was useful.

Dr. GOSSAGE replied and the meeting terminated.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

African Tick Fever.

A MEETING of this society was held on June 19th, Sir PATRICK MANSON, *the President*, being in the chair.

Dr. C. F. HARFORD read a paper on African Tick Fever with special reference to its clinical manifestation and its relation to relapsing fever of India and other parts of the world. He said that the question must be raised as to how far tick fever had existed, for instance, in such a territory as Uganda for many years past, and whether the increase was as rapid as it seemed, or whether the increase was chiefly apparent and was really due to the fact that it was not recognised before. One point was quite clear and that was that the systematic examination of the blood, which was now being carried out by many medical men in Africa, made it possible to diagnose many diseases with certainty in a way which was not possible before. The society had considered on various occasions the special characters of spirochæta Duttoni which was generally acknowledged to be the cause of African tick fever, and he would only venture to express his opinion that the organism belonged to the protozoa, and that whilst there, no doubt, were slight morphological differences between that parasite and the one usually known as spirochæta Obermeieri, yet those did not appear to be greater than, if as great as, the differences between various forms of malarial parasites. He took it as proved that the form of fever, which for the sake of convenience he referred to as tick fever, was conveyed by the tick ornithodorus moubata. He then considered the series of notes of 66 cases which had been most kindly supplied to him by Dr. A. R. Cook and Dr. J. H. Cook of the Church Missionary Society, Uganda. Of the 66 cases 39 were males and 27 females; and again, out of the total number 46 were adults and 20 were children. Of the total number 57 were cured and nine were fatal. Blood examination was recorded in 57 out of the 66 cases and spirochætæ were found in all of these except one. In one of the cases only one spirochæta was found after a prolonged search, but in others they appeared to have been fairly plentiful. In some cases where spirochætæ

Indeed, the tone of cardiac muscle might be regarded as a method of storing up a reserve of force which was liberated on dilatation of the heart. The *action of the cardiac tonics* was mainly to cause an increase of muscular tone. In considering human hearts it was found that the phenomena *of* dilatation of the heart conformed with the theory as to the influence of tone. In the *dilated* heart the *diastolic relaxation* was obviously greater than in the normal heart, or, in other words, tone was diminished. In association with that they found excitability increased, as shown by the increased rate and the frequency with which extra systoles occurred. Conductivity was probably also increased, since they found no lengthening of the interval between the time of contraction of the auricles and that of the *ventricles, although* the heart was beating more rapidly. Experiments on animals showed that the recovery of conductivity was a gradual process requiring a certain amount of time and it was probable that the same was *true of human beings*, especially as a very considerable time was required for the recovery *of conductivity in cases where it was depressed*. In the dilated heart contractility was also increased, *since the heart had to perform more* work to maintain the circulation, and in the majority of cases the *circulation* was in a *fashion maintained*. The intense *labour* performed by the heart, even when ineffectual, was a common clinical experience in cases of dilatation. This excessive expenditure of energy was always liable to be followed by exhaustion and then the heart would fail in its task of keeping the circulation up to a sufficient standard. Since the dilated, toneless heart had to work too hard and was always in danger of failing, their object in treatment must obviously be to *restore some of the lost tone*. It was, *of course*, possible that that could be done by mechanical means; with diminished work there might be diminished pressure within the cardiac chambers and that *might* help in the *restoration* of tone. At any rate, the beneficial effects of rest and bleeding in cases of dilatation of the heart had *long* been recognised. Mechanical measures were, however, often *insufficient and had to be supplemented by the use of drugs*. Unfortunately, the action of drugs was seldom a simple affair and the *results* of *experiments* on animals were not always borne out in the clinical treatment of patients. The drugs employed in the treatment of dilatation and heart failure belonged mainly to the digitalis group and it was of great importance to understand their exact mode of action. Digitalis and strophanthus had in animal experiments a very similar action, except that digitalis constricted the vessels while strophanthus did not, and thus digitalis had the greater effect of the two in raising the blood pressure. Among other vessels, however, it also constricted the coronary arteries, and the flow of blood through the coronaries was of immense importance to the heart, increase of flow leading to increased size of the contraction and *vice versâ*. Even increased tension in the coronaries with an indifferent fluid, such as oil, might cause a quiescent heart to start beating again. Cushny pointed out that digitalis had two opposing actions on the heart—(1) as a stimulus and (2) as a bridle—, *and that it was difficult to predict* which result would follow *its exhibition* in a particular case. It seemed possible that a very large *part of the action of digitalis* might be explained *by regarding* it as a powerful stimulus to the heart, very similar to the interrupted *electric current in Porter's* experiments. It would stimulate the vagus, the muscle directly, and tone. In the *hearts of animals* the *first* effect *of* digitalis was usually to increase the size of the individual contractions, and at that stage the diastolic *relaxation* was often more marked, or, in other words, there was some diminution of tone. *Together with* those phenomena the rate of the heart was sometimes increased. Later there was a *decided and gradual increase of tone*, usually a diminution of rate and gradual decrease in size of the contraction. Still later the rate *increased again* with a *further* increase in tone; then delirium cordis might supervene and the heart finally stopped *in a condition of* excessive tone. The resemblance of all that to the phenomena accompanying gradually increasing tone in Porter's researches *on the* auricle of the tortoise was very striking, the main difference being that with digitalis the *whole process to the stoppage* of the heart in excessive tone or tetanus took much longer. Closer investigation had *shown* that excitability to direct stimulation was decreased in digitalis poisoning, while conductivity was also diminished even some*times to* the extent of causing a block between auricle and ventricle. Since Porter had demonstrated that increase of tone was sufficient to produce decrease of contractility (as *shown* by the diminished *size of the beats*) and decrease of conductivity, the action of digitalis in lessening *those two properties* must be partly due to its effect in augmenting the muscle tone and might be entirely due to the *alteration of tone*. The diminution of excitability was probably also partly due to the same cause, an increase of tone. Loss of tone was certainly associated with increased excitability so that it was probable *that increase of tone would lead to* decrease of excitability. The increased rate which appeared *later* in digitalis poisoning was probably *due to* direct stimulation of the muscle by the digitalis, while the terminal *delirium cordis* would have the same causation as the similar phenomenon noted by Porter with increased tone, the ventricle *not contracting as a whole, but isolated portions of* the wall contracting separately owing to decrease of conductivity. *Indeed, Sowton noticed that samples of digitalis* that caused marked delirium cordis usually also brought *about a striking decrease of conductivity as* shown by the number of the auricular beats that were not conducted to the ventricle. In that connexion it was *interesting to note that* Muskens had offered a similar explanation for the occurrence of *alternating* action of the *heart in digitalis* poisoning. That action where the beats were alternately large and small, although the *intervals* between *them* were approximately equal, had usually been attributed to failure of contractility but Muskens regarded it as resulting from a depression of conductivity which led to isolation of portions of the ventricular wall, and after every normal beat a contraction of only part of the ventricle. From animal experiments, *then, it seemed that digitalis acted at first as a stimulus* to the heart, increasing the contractility and often the rate, possibly also conductivity and excitability. Later it stimulated tone and with increased tone there was diminution of contractility, excitability, and conductivity. In human *beings the amount of the drug that* reached the heart must be small and the amount that it was possible to administer *was limited by the irritant effect of digitalis* on the gastro-intestinal tract. It was to be remembered, however, that the drug was cumulative in *its action so that a considerable* effect might be produced by small doses continued over a long time. The irritant action on *stomach and intestine* was not observed with strophanthus and that possibly constituted one of its dangers. The early stage of stimulation was difficult to demonstrate in clinical work, *although it* might be of importance. *Practically, however, as Mackenzie* had recently pointed out, it was only in cases of dilatation that marked results were obtained, or in other *words that* digitalis acted therapeutically mainly on the function *of* tonicity. Improvement often occurred quite *suddenly* although the drug might have to be administered for several days before any effect was produced. Very rapidly there might be a sensible decrease in the dilatation, the œdema might diminish, the liver shrink in size and there might be a decided rise in the blood pressure and in the amount of urine secreted. Coincident with the decrease in the dilatation the rhythm became less frequent and any irregularity was lessened. The decrease in frequency and irregularity was, no doubt, partly due to diminution of the excitability, though direct stimulation of the vagus might be the cause of a decreased rate of stimulus production and so a less frequent rhythm. Mackenzie had shown that a normal heart, or a diseased heart which was not at the same time dilated, was practically unaffected by such doses of digitalis as could be given to men by the mouth. That was perhaps only what should be expected since it was probable that a smaller dose would be required to increase the tone of a dilated heart (i.e., where tone was much diminished) than to add to the tone of a heart where *it* was already at the normal standard. The excitability of tone varied with different *circumstances in animals* and no doubt had the same variability in human beings. It was in cases of recent dilatation, or recent *increase of dilatation* when the muscle was healthy that the tone of the human heart seemed especially *susceptible to the influence* of digitalis. Experimentally tone diminished contractility and conductivity and *not improbably* excitability also, so *that* they would expect digitalis when it increased *tone in men to decrease* those other properties. Its effect on excitability was apparent; the diminution of *rate and of irregularity* showed its restraining influence. There were, however, [illegible] lar instances where a heart which was [illegible] became irregular under the administration of digitalis. That irregularity was of several kinds, of which the commonest form was the development of a "bigeminal action" where an extra-systole followed each normal beat. A bigeminal action was not uncommon in over-excitable hearts where no drug had been employed, and a probable explanation of its occurrence after digitalis was that the decreased rate had allowed a hidden bigeminal action to appear. For that explanation to be applicable it was necessary that the interval before the extra-systole should be longer than the intervals between adjacent beats before the administration of digitalis. Hering showed that a bigeminal action might be made to disappear by giving atropine, its disappearance coinciding with the time when the normal rhythm became so rapid that a normal beat occurred exactly at the moment when the extra-systole would be expected: any rate faster than that was regular, while any slower rate, as shown when the effect of the atropine wore off, was of the bigeminal character. A bigeminal action was not necessarily constant and they would not always expect a constant bigeminal action in cases occurring after digitalis. It was not necessary, therefore, to assume that in these cases the digitalis caused an increase of excitability contrary to its usual action of decreasing excitability. A second type of irregularity after digitalis might be produced by the occurrence of isolated extra-systoles. That might, of course, be merely a consequence of reduction of rate, since with a rapid rhythm there was very little opportunity for the occurrence of extra-systoles. Another type of irregularity after digitalis had to do with the depression of quite a different property of the muscle—namely, conductivity. There was abundance of evidence that digitalis depressed conductivity in animals and Mackenzie had shown that the same action took place in human beings provided that conductivity was somewhat depressed before the drug was given. In some cases there might be an apparent improvement in conductivity after digitalis owing to the slower rate giving more time for its recovery. In view of the small doses that it was possible to administer it is not surprising that depression of conductivity by digitalis was only observed clinically in cases where there was already evidence of its being damaged. The effect of digitalis on contractility was more difficult to estimate. There was no doubt of the more efficient working of the heart when digitalis had been given in suitable cases. That was partly due to the mechanical advantage of the decreased dilatation brought about by increased tone and partly due to the fact that the slower rate allows a longer time for the contractility to recover. In animal experiments, however, it was clear that both an increase of tone and the administration of digitalis resulted in a diminution of contractility. That drug, too, often produced an alternating action of the heart which had been supposed to be the expression of damaged contractility. The evidence of depression of contractility by digitalis in the human heart seemed sufficiently clear and they could have no doubt of that action of digitalis from the results of animal experiments. Probably only those patients whose contractility was already depressed would show any further recognisable lowering with digitalis. The foregoing arguments afforded sufficient justification for affirming that tone played the same important rôle in the human heart as in the animal and that increase of tone had the effect of diminishing the other properties of the cardiac muscle—namely, contractility, excitability, and conductivity. That conclusion, too, was of considerable clinical importance. The recognition of loss of tone as the important factor in dilatation of the heart was a great advance, and they now found in addition that many of the phenomena associated with dilatation were directly due to that loss of tone. The dependence of the other properties on tone afforded a remarkable method of self-regulation in the heart, so that it was enabled to do just the amount of work which was required of it. Some light was also thrown on the obscure subject of the action of digitalis on the heart, though it could not be said that that question was completely answered. Part of the action of digitalis was evidently secondary to its influence on the muscle tone, but how much of the damage done to contractility, conductivity, and excitability came from increased tone and how much from stimulation of the vagus could not at present be estimated. The narrowing of the coronary vessels would probably also tend to depress the properties of the cardiac muscle to an extent that was incapable of exact appreciation. It was important to note that in the case cited the digitalis had greatly improved the patient's general condition as well as the general working of the circulation in spite of the grave depression of conductivity and the occasional dropping out of ventricular beats. Evidently the improvement resulted from the increase of tone and these facts received their simplest explanation in the conception of tone that he (Dr. Gossage) had advanced.

Dr. J. MACKENZIE said that the paper had helped him to understand why there was an increase in the rate of the heart's beat in cases where sudden dilatation had taken place.

Professor A. R. CUSHNY said that it was interesting to find Dr. Gossage going back to the view that the action of digitalis on the heart may be due to what was called its elasticity, which was very much the same thing as the tonicity described by Dr. Gossage.

Dr. A. MORISON said that in the discussion of the subject they could not eliminate the influence of the nervous system or that of the blood.

Dr. H. A. CALEY said that the value of the paper by Dr. Gossage consisted in the evidence which it contained that digitalis was indicated in cases of cardiac myasthenia with dilatation, and if digitalis failed to do good in such circumstances causes such as degeneration of the coronary arteries or actual degenerative changes in the myocardium itself must be considered.

Dr. LEES laid stress upon the importance of ascertaining the true size of the heart in cardiac conditions which he said could quite easily be done by careful percussion. The use of digitalis was not indicated in cases of dilated heart due to an acute toxic condition, but where the condition was chronic then digitalis was useful.

Dr. GOSSAGE replied and the meeting terminated.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

African Tick Fever.

A MEETING of this society was held on June 19th, Sir PATRICK MANSON, the President, being in the chair.

Dr. C. F. HARFORD read a paper on African Tick Fever with special reference to its clinical manifestation and its relation to relapsing fever of India and other parts of the world. He said that the question must be raised as to how far tick fever had existed, for instance, in such a territory as Uganda for many years past, and whether the increase was as rapid as it seemed, or whether the increase was chiefly apparent and was really due to the fact that it was not recognised before. One point was quite clear and that was that the systematic examination of the blood, which was now being carried out by many medical men in Africa, made it possible to diagnose many diseases with certainty in a way which was not possible before. The society had considered on various occasions the special characters of spirochæta Duttoni which was generally acknowledged to be the cause of African tick fever, and he would only venture to express his opinion that the organism belonged to the protozoa, and that whilst there, no doubt, were slight morphological differences between that parasite and the one usually known as spirochæta Obermeieri, yet those did not appear to be greater than, if as great as, the differences between various forms of malarial parasites. He took it as proved that the form of fever, which for the sake of convenience he referred to as tick fever, was conveyed by the tick ornithodorus moubata. He then considered the series of notes of 66 cases which had been most kindly supplied to him by Dr. A. R. Cook and Dr. J. H. Cook of the Church Missionary Society, Uganda. Of the 66 cases 39 were males and 27 females; and again, out of the total number 46 were adults and 20 were children. Of the total number 57 were cured and nine were fatal. Blood examination was recorded in 57 out of the 66 cases and spirochætæ were found in all of these except one. In one of the cases only one spirochæta was found after a prolonged search, but in others they appeared to have been fairly plentiful. In some cases where spirochætæ were said to be scanty it was clear that the case was one of a relapse and not of the primary paroxysm, and in some cases it was a case of a second attack of the disease. In the three cases which died within a few hours of admission it was noted in one case that the spirochætæ were "teeming," and in another "intense infection, three to four in a field." In a third they were "abundant." In others which died either on the first or second day after admission it was only noted that spirochætæ were found. As might be expected, a large number of the cases showed only single paroxysms. That was partly to be accounted for by the fact that the patients recovered after the first sufficiently to leave the hospital and did not come back a second time. In many cases, however, it was believed that the cases were second attacks which always seemed to be greatly modified. There was a great variation in the times intervening between the relapses, though it might be taken as a general rule that the first relapse came on after an interval of about seven or eight days, the later ones being more irregular in their time of occurrence. Dr. J. H. Cook noted that the number of relapses was variable, on an average perhaps four or five, but he had known as many as nine or ten sometimes. He stated that sometimes without pyrexia in the later relapses there occurred at the expected time when the relapse was due malaise, headache, or gastric upset. He said the usual interval was eight days and that corresponded with the usual period of incubation. In other cases it was even longer, but not often shorter except in cases of double infections. As regards the height of temperature, four cases reached 106° F. or above, 13 cases reached 105°-105·9°, 17 cases reached 104°-104·9°, and 13 cases reached 103°-103·9°. As regards other symptoms, rigor occurred in 21 cases. In 24 cases there was no rigor, whilst in the remaining cases the question of rigor was not referred to. It was noted that the spleen was enlarged in 35 cases and that there was no enlargement in 20 cases, and though it was probable that most of the patients had been liable to malaria, yet it seemed justifiable to regard enlargement of the spleen as a common symptom of the disease. Vomiting was noted as a prominent symptom in 30 cases and diarrhœa in nine cases, delirium being only referred to in six cases. From these figures it appeared that beyond the usual symptoms of fever there was often some gastro-intestinal disturbance but there were no other symptoms which could be regarded as pathognomonic of the disease. Miscarriage appeared almost always to take place in cases of pregnancy and two cases appeared among the cases given. Iritis was a frequent complication. It was usually plastic and very painful and lasted about five weeks, and the risk of adhesions was great. The tendency was to get absolutely well with careful treatment. There were three or four cases of serious irido-cyclitis from tick fever. The prognosis here, too, was hopeful and recovery of sight also perfect. Facial paralysis was a serious complication which he had noted in three cases. The prognosis was hopeful and duration as a rule was from six to eight weeks. But perhaps the most interesting of Dr. J. H. Cook's notes was his reference to the possible connexion between tick fever and blackwater fever. He had noted that in two cases. In the latter case no spirochætæ were found, though the case seemed to be one of tick fever. In neither of those cases was there at the time any sign of malarial infection. Dr. Cook raised the question whether it was possible that there might be any special relation between tick fever and black-water fever such as was usually traced between blackwater fever and malaria. On the other hand, Dr. Cook alluded to the suggestion made by Dr. L. W. Sambon that blackwater fever might be conveyed by the bite of ticks, and he suggested that possibly the same tick communicated parasites both of tick fever and of blackwater fever, if the latter fever could be said to be due to a distinct organism. He (Dr. Harford) was inclined to think that there might be many causes for the occurrence of blackwater fever. Malignant malarial infection seemed to be the primary cause, whilst many other circumstances, such as chill, the taking of an unusual dose of quinine in those especially susceptible to its action, might be accelerating causes, and it was possible that a paroxysm of tick fever might be the determining cause in those cases. Dr. J. H. Cook did not believe that immunity existed either naturally or acquired by attacks. He knew many people who had had two distinct attacks, though he remarked that second attacks were usually less severe and with fewer relapses than in the case of primary attacks. He (Dr. Harford) had hoped to have been able to institute a comparison between the relapsing fever of Africa and that of India and other parts of the world, but the amount of material which Dr. Cook had supplied to him had required so much arrangement that it had left little time to deal with other parts of the world. The charts which had been published by the Liverpool School of Tropical Medicine corresponded very closely with those furnished from Uganda and clearly described the same disease. He had no doubt himself that tick fever was practically identical with the relapsing fever of other parts. Differences there might be in the clinical features of the disease, as in the morphological characters of the parasite, but he hoped that they would dismiss the titles of tick fever or spirillum fever and call it relapsing fever.

Dr. L. W. **SAMBON** discussed the paper from an epidemiological point of view and put forward his views on the parasitology of the disease.

Dr. F. M. **SANDWITH**, speaking from his experience of relapsing fever in Egypt, remarked that in the African cases mentioned in the paper jaundice was only present in one case, whereas elsewhere jaundice was regarded as one of the important symptoms.

Dr. A. W. G. **BAGSHAWE** (Uganda) observed that slight jaundice was a fairly common symptom in tick fever.

Dr. A. **CASTELLANI** (Ceylon) said that he had used atoxyl and quinine cacodylate in the treatment of six cases.

Dr. G. C. **LOW** considered that the cases described in the paper as double infection were not due to the same parasite.

Mr. C. J. **BAKER** (Uganda) described the pulmonary symptoms which he had noticed in the disease and narrated how patients suffered from dyspnœa and had all the appearances of being affected with pneumonia.

Dr. L. **HILL** mentioned that relapsing fever was prevalent in Ireland for a short time and then disappeared entirely.

The **PRESIDENT** asked whether anything had been done in the way of introducing serum treatment for relapsing fever. By means of experiments on animals it had been found possible to abort and to prevent relapsing fever in animals.

After Dr. **HARFORD** had replied the meeting terminated.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Congenital Vaginal Cyst.—Rupture of Uterus.—Treatment of Puerperal Septicæmia.

A MEETING of this society was held at Liverpool on June 19th, Dr. A. J. **WALLACE** (Liverpool) being in the chair.

Dr. W. **BLAIR BELL** (Liverpool) related a case of Large Congenital Cyst of the Vagina occurring in a married woman, aged 21 years, who had been delivered without difficulty of a full-term child. The cyst was of the size of a cocoanut and lay between the uterus, bladder, and anterior vaginal wall. It was removed with some difficulty on account of its deep connexions.

Dr. W. E. **FOTHERGILL** (Manchester) communicated two cases of Abdominal Hysterectomy for Complete Rupture of the Uterus. The first case was that of a woman, aged 32 years, who was admitted to St. Mary's Hospital with a ruptured uterus produced during the performance of podalic version. She was very collapsed from hæmorrhage and on careful vaginal examination under anæsthesia a deep tear of the cervix extending high up on the right side was discovered. It was too inaccessible to be dealt with per vaginam and abdominal section showed the laceration to extend as high as the origin of the right Fallopian tube, involving the peritoneum. There was a considerable amount of blood in the abdomen. The entire uterus was removed and the patient made a good recovery. The second case occurred in a woman, aged 30 years, multipara, who was admitted to hospital after unsuccessful attempts had been made to deliver a brow presentation. The head of the child was found to be in utero, the trunk and limbs in the abdomen. Podalic version was first performed and the child was delivered with considerable difficulty, followed by the manual detachment of the placenta. An hour later abdominal hysterectomy was carried out. The lower uterine segment was very much bruised and a complete tear ran transversely, involving the right posterior aspect of the uterus. The patient made a satisfactory recovery.

Dr. A. KNYVETT GORDON (Monsall) read a paper on Some Problems suggested by a Series of cases of Puerperal Sepsis of Advanced Type. He confined his remarks to the curative treatment of severe cases only, based on an investigation of 250 cases treated in the Monsall Fever Hospital. He first of all dealt with the type of case where the patient is desperately ill, where the extent of septic absorption is great, either of toxins or organisms, and where the only obvious local signs are sub-involution and endometritis, with some abdominal distension. Half of these patients had streptococci in the circulating blood. Dr. Gordon drew attention to the two opposed schools of treatment: in the case of one reliance was placed solely in vaginal and uterine douching, avoiding anything of the nature of active interference with the interior of the uterus. He thought that it was very necessary to consider this opinion seriously, founded as it was on the teaching of Metchnikoff, that between the organism and the system was a wall of leucocytic infiltration the integrity of which must not be disturbed. The opposite school regarded the infected uterus just as a wound in any other situation, and would treat it accordingly—viz., by active disinfection. He maintained that in puerperal sepsis of the type which he had defined the granulation wall was useless, or as Sir William J. Sinclair had happily put it, had been scaled or breached. When he first began to treat these cases by douching alone, the mortality was 46 per cent. Since the employment of more active measures the mortality had fallen to 24 per cent., where it had remained for three years. It was his practice to scrape thoroughly the interior of the uterus with a large sharp curette, followed by the application of undiluted izal solution on swabs. In regard to pelvic cellulitis resulting from deep, infected tears of the cervix he suggested that incision of the inflamed area and drainage per vaginam should be adopted. He had never performed hysterectomy in the early stage of puerperal sepsis and only five times as a last resort, all unsuccessfully. His experience, therefore, of this procedure was too limited, but he failed to see how such a practice could be adopted successfully without removing a large number of uteri unnecessarily. A very important administrative problem was also considered. Where ought these cases to be treated? He thought that they should go to a fever hospital administered by a resident superintendent and that a gynæcologist who is not too busy to attend regularly should be attached to the staff. Care should be taken to select and to train the nurses, a certificate only being awarded after at least two years' satisfactory work in the wards, coupled with attendance at systematic and clinical lectures, the theoretical knowledge being also tested by examination.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on June 19th, Dr. W. J. Tyson (Folkestone), the President, being in the chair.—Eight candidates were elected, making a total roll of more than 400. After an address from Dr. James F. Goodhart the President said that he wished the profession generally would more thoroughly understand the work that the society was doing for the promotion and extension of the knowledge of all health resorts, English and foreign. The efficient study of health resorts, from a balneological and climatological standpoint, required much time and experience. The study took in the whole range of medicine, and it required well-trained and thoughtful physicians to put into practice all the advantages that were possible in our well-equipped spas and marine towns. The advising of the choice of a health resort should be in the hands of those who know intelligently the various qualities and adaptabilities of the many spas. To send patients away, often to a distance or abroad, without very carefully considering all the conditions of the patient and the place recommended seemed to be unscientific treatment; and yet this method was not infrequently followed. The society was ever willing to communicate its special knowledge to those who required it and, he trusted, would in the future be looked upon more and more in the light of a consultant in its own special department.—Dr. Leonard Williams remarked that it was no idle boast to say that before the inception of this society the study of balneology and climatology did not exist in this country. The society had endeavoured and had succeeded in lifting these therapeutic measures out of the mire of empiricism in which they had too long wallowed into the domain of rational, straightforward, scientific branches of professional work. The papers which had been read before the Fellows and the articles which had appeared in the *Journal of Balneology and Climatology* during the 12 years of existence of the society were real contributions to the elucidation of the many problems which surrounded the therapeutics of baths and climates. These therapeutic measures were destined in the future to play a very large part in the treatment of chronic disease and they had deserved well of their professional brethren in placing at their disposal the results of the work which was being done in these matters.—Mr. Ernest Solly (Harrogate) was elected President of the society for the coming year, with Dr. Septimus P. Sunderland and Dr. F. A. de T. Mouillot as secretaries.—Sir Thomas Barlow and Mr. George Eastes were entertained at the annual dinner of the society.

Reviews and Notices of Books.

School Hygiene. By ROBERT A. LYSTER, M.B., Ch.B. Birm., B.Sc. Lond., D.P.H., B.Sc. Public Health. London: W. B. Clive. 1908. Pp. 360. Price 3s. 6d.

ONE of the most important movements of recent times from a national point of view is that which has had for its object the application of sound principles to secure improvements in the nurture and education of children. Statesmen, medical practitioners, and educationists have combined to work for this object and many much-needed reforms have resulted. The subject of school hygiene is obviously one in which it is essential that the teachers should be thoroughly grounded in order that they may be enabled to adapt their instruction to the capacities and needs of the children and also be able to give elementary instruction in personal hygiene. The subject is, moreover, one which demands at any rate an elementary knowledge of many physiological and medical problems as well as of sanitation and the general laws of health. A text-book intended for teachers must therefore afford this information in language stripped as far as possible of abstruse technicalities and in simple explanatory style. Dr. Lyster's book is calculated to supply the necessary information. It is clearly written, takes nothing for granted, and yet is never diffuse or irrelevant. It is well illustrated by many figures, diagrams, and reproductions of photographs. It is obviously the outcome of a practical knowledge of the subject and of experience in lecturing to teachers.

The book is divided into three parts. The first of these is devoted to the school building and deals with the questions of site, construction and arrangement of the building, lighting, heating, and ventilation. The sanitary arrangements advisable and necessary for schools are considered in detail and the various methods of effecting them are discussed. The second part deals with physical training and the laws of health. The various forms of school fittings are described. Different varieties of desks are figured and criticised. The bad effects of many of the ordinary forms are clearly pointed out. It is admitted that the problem of a universally satisfactory desk has not yet been solved but that certain of those now in use, especially those which are adjustable, are useful and no likely to cause any harmful results if the scholars are no kept seated for long periods at a time. Postures in regard t school work are considered, especially as to reading writing, standing, and receiving instruction. A useful section is devoted to breathing exercises and their importance receives full recognition. The eyes, ears, throat, and nose are considered in connexion with school work and the prevention of injuries to the eyes at school is considered. In a chapter on personal hygiene the clothing and feeding of children are discussed and the amount of sleep advisable at different ages is set forth. Personal cleanliness and the care of the hair and of the teeth are also discussed, and useful recommendations are given. The third part of the book is devoted to medical supervision and school medicine and surgery. Some useful general information is supplied in regard to the mentally defective children and to common ailments and diseases. Epidemic diseases come in for special description, and the closing of schools as a result of outbreaks of such diseases is discussed, together with the measures necessary for disinfection.

Dr. Lyster's book affords a great deal of information within very convenient compass and should be a useful small manual for teachers and for others interested in school hygiene.

The Borderland of Epilepsy. By Sir WILLIAM GOWERS, M.D. Lond., F.R.S. London: J. and A. Churchill. 1907. Pp. 118. Price 4*s.* 6*d.* net.

FOR the most part the substance of this work has appeared, reported as lectures, in the medical journals.

The first chapter opens with a discussion on the mechanism of unconsciousness. In certain cases there may be a diminution of the due supply of nutrition to the brain, in others a diminution of intracranial pressure, or again a discontinuity of conduction at the junction of the neurons. Cases are related which suggest the possibility of some sort of connexion between syncope and epilepsy and which present strong evidence of repeated cardiac syncope disposing to epilepsy. Diagnosis between syncope and minor epilepsy is sometimes difficult, but sudden, intense, and brief sleepiness with dusky complexion is not met with in syncope and is significant of epilepsy. Cardiac auræ in epilepsy are particularly perplexing and may easily mislead the physician. In syncope the more distinctive symptoms consist in the gradually on-coming of pallor and faintness with failure of sight and gradually approaching unconsciousness. No rigidity occurs and recovery is with a slowly lessening sense of faintness and without mental confusion.

The second chapter is devoted to a description of "vagal attacks," this being a useful designation for prolonged seizures the symptoms of which consist chiefly in disturbance of some of the functions of the pneumogastric nerve. On the sensory side there are feelings of gastric, respiratory, and cardiac discomfort. There are also slight mental change, coldness of the extremities, with, perhaps, some sensory impairment and often slight tetanoid spasm. The author suggests that such attacks may be minor epileptic seizures extended in time. In these states attention to the general health is of the utmost importance. Bromides seem to exert little direct influence. Where vaso-motor spasm forms part of the attack nitro-glycerine is of service. Chapters III. and IV. contain an account of aural vertigo and of its differentiation from minor epilepsy, together with the histories of a few patients which suggest that the relationship of the two diseases may sometimes be closer than a mere coincidence. The process in vertigo may provisionally be conceived "as an upward 'discharge' from the lower centres, acting on the cerebral cortex and inducing in it motor and sensory activity by which consciousness arises of the features of the attack." Chapter V. deals with the relations of migraine and epilepsy. There are an undoubted alternation and co-existence of these maladies, similarities in their premonitory disturbances, and there exist instances in which migraine has appeared to develop into epilepsy, yet the differences are definite and distinctive. The warning of the epileptic fit occurs immediately before the seizure; that of migraine lasts for from 10 to 30 minutes and has very special characteristic features. Clonic spasm is unknown in migraine, while its pain is distinctive. In Chapter VI. there is an account of some sleep symptoms, such as night terrors, somnambulism, and narcolepsy.

This small work is of the utmost interest and is written in the well-known fascinating style of the author. We venture to express a hope that it may be the prelude to a larger work on the same subject.

Cancer; Relief of Pain and Possible Cure. By SKENE KEITH, M.B. Edin., F.R.C.S. Edin.; and GEORGE E. KEITH, M.B., C.M. Edin. London: Adam and Charles Black. 1908. Pp. 155. Price 2*s.* 6*d.* net.

IN reading this work we have been struck with the very candid attitude of the authors. They tell us all that they know about the method of treatment which they have employed, and they give details of a large number of cases which they have treated, and in no way do they claim that they have discovered a cure for cancer; they merely say that they have found that the use of the injections which they employ has been followed in nearly all cases by marked improvement in the amount of pain, by diminution, and in a few, a very few cases, by disappearance, of the growth. The injections employed consisted of iodipin, arseniate of iron, cacodylate of iron, and cinnamate of sodium. It may well be worth while to try such methods as this in cases unsuitable for operation or where the patients decline to submit to operative measures. The attitude adopted by many that if operation is impossible nothing can be done, appears to us to be unwise. It is no doubt due to the hasty and extravagant claims put forward by many. The authors of this book endeavour to state only facts, and the introduction on the difficulties of treating cancer is very judicious. It is interesting to note that trypsin was extensively employed by the authors for a year and they came to the conclusion that it was not only useless but also dangerous.

Les Pseudo-Bacilles Acido-Résistants. Critique des Méthodes de Coloration du Bacille Tuberculeux. Revision du Groupe des Bacilles dits Acido-Résistants. Par le Dr. ANDRÉ PHILIBERT, Interne Lauréat des Hôpitaux de Paris (Médaille d'Or Médecine, 1907), &c. Paris: G. Steinheil. 1908. Pp. 143. Price fr. 4.

THE differentiation of the various micro-organisms which belong to the rapidly increasing class of acid-fast bacilli is a matter of considerable importance whether it be regarded from the point of view of the clinician or from that of the medical officer of health. This work from the bacteriological laboratory of the Faculty of Medicine of Paris by Dr. Philibert is therefore of interest. In the past there has been some laxity in the use of the term "acid-fast"; sometimes this expression has been held to embrace the further quality of resistance to decolourisation by absolute alcohol and sometimes it was considered apart from this latter quality. By rigidly defining the method of staining and measuring the amount of resistance to decolourisation by acids and alcohol it is possible to arrive at results of clinical value and to avoid many of the pitfalls which have arisen in great part from the use of methods which have been largely modified from those originally proposed by Koch and Ehrlich for the demonstration of the tubercle bacillus. The bacillus tuberculosis if stained with hot carbol-fuchsin for ten minutes will withstand decolourisation by nitric acid (1 to 3) for two minutes, followed by the action of absolute alcohol for from three to five minutes, and does not become [illegible] h a simple counterstain. This method may, according to Dr. Philibert, be trusted to distinguish between the bacillus tuberculosis and the large number of morphologically similar, but not so resistant, organisms which have been found in the smegma, urine, serous effusions, blood, sputum, sebaceous material, cerumen, pus, and occasionally in the organs of the corpse. These less resistant organisms the author groups as accidentally acid-fast in contradistinction to the tubercle bacillus which he considers to be hereditarily acid-fast. To the clinician these results are satisfactory. Unfortunately, the hereditarily acid-fast group includes the bacillus lepræ and the bacilli found in butter, fodder grass, dung, and so on, which are so liable to appear in milk and milk products and give rise to errors which if not embarrassing to the physician are so to the medical officer of health. No staining method for the differentiation of members of this group, which are held to be closely related to one another, is given.

The book gives a very complete account of the various accidentally acid-fast bacilli which have been described and the supposed cause of the acid-fast character is discussed. The author concludes that the resistance to decolourisation is not due to fat, fatty acids, or cholesterin but he fails to establish the true cause. He does not deal with the question of the occurrence of forms of the tubercle bacillus which are not acid-fast. There is a good bibliography but, as is unfortunately so common in French works, no index.

The Production and Handling of Clean Milk. By KENELM WINSLOW, M.D.V., B.A.S. (Harv.); formerly Instructor in Bussey Agricultural Institute and Assistant Professor in the Veterinary School of Harvard University; Chairman of the Committee on Milk of the Washington State Medical Association, &c. London: Baillière, Tindall, and Cox; New York: William R. Jenkins Co. 1908. Pp. 207. Price 10*s.* 6*d.* net.

So far as the production, transportation, and distribution of milk are concerned, it may be said that, on the whole, the methods in force in the United States are superior to those which are adopted in this country. Therefore a book dealing with the subject written by an acknowledged American authority may well contain matters of instruction and interest for English readers. Such a work is that by Dr. Winslow who treats the milk problem from various standpoints. His main object, however, is to arouse the public to the dangers of contaminated milk and to lay stress on the fact that it is impossible to produce and to sell clean milk except at a considerably increased price. Many parts of the book deal with points which have been discussed so thoroughly already that it would be superfluous to summarise them. Of the chapters dealing with matters of less common interest we may mention that on "feeding for milk," in which Dr. Winslow points out that by suitable food and by judicious breeding it has been found possible to evolve an animal giving milk 1 per cent. richer than that common to its breed. The housing and care of cows are discussed in detail, while to the handling of milk and cream, as befits the importance of the subject, is devoted the longest chapter of the book. The numerous devices and inventions in use in the United States for carrying, cooling, straining, separating, and sterilising milk are explained adequately, and it is mentioned that if paper bottles came into use much of the trouble and expense now entailed by bottling milk would be done away. Some space is given to a consideration of the cost of producing and distributing clean milk, but as conditions differ somewhat widely in the United States and in this country the figures quoted will hardly apply to Great Britain. As for milk distribution, the methods in vogue in America are set forth, but again when this matter is considered the fact must be borne in mind that in American cities bottles are very largely used in the distribution of milk and that ice or some cooling apparatus is almost invariably employed both in transportation and in distribution. Milk inspection and the various modes of testing milk are treated at some length. In the appendix is to be found a considerable amount of valuable information regarding dairy cows and their management. The portion referring to barns and milk rooms is particularly good. Dr. Winslow writes favourably of milking machines and quotes the opinion of a well-known American dairyman to the effect that in time these machines will supersede milking by hand.

The book ends with the outline of a scheme for the control, supervision, and inspection of a city milk-supply, which, though intended for an American town, will well repay the attention of English readers. A special feature of Dr. Winslow's book is the number and excellence of its illustrations.

LIBRARY TABLE.

Clinical Lectures on the Surgical Diseases of the Urinary Organs. By P. J. FREYER, M.A., M.D., M.Ch. R.U.I., Surgeon to King Edward VII.'s Hospital for Officers and to St. Peter's Hospital; Consulting Surgeon to Queen Alexandra's Military Hospital; late Examiner in Surgery at the Durham University; Lieutenant-Colonel Indian Medical Service (retired). London: Baillière, Tindall, and Cox. 1908. Pp. 425. Price 12*s.* 6*d.* net.—In these clinical studies the greater part of the surgery of the urinary organs of the male is expounded. Many of those who heard them delivered at the Medical Graduates' College and at St. Peter's Hospital will be glad to have them in volume form. The most important chapters are those dealing with the enucleation of hypertrophied prostates. Whether Mr. Freyer was or was not the inventor of the operation we need not now discuss; but it is at least indisputable that to Mr. Freyer is due the present popularity of the enucleation of the prostate, and it is useful to have this latest exposition of his views. The lectures on the removal of stone from the bladder are also good. The book is well illustrated.

Pelvic Inflammations in the Female. By THOMAS WILSON, M.D. Lond., M.Ch. Birm., F.R.C.S. Eng., Obstetric Officer to the General Hospital, Birmingham. Bristol: John Wright and Co. 1907. Pp. 36. Price 3*s.* 6*d.* net.—Dr. Thomas Wilson chose the very important and practical subject of Pelvic Inflammations in the Female for the Ingleby lectures last year and has since published them in book form. His observations are based upon some 1092 cases seen as out-patients, a large number of post-mortem examinations, and a series of 307 cases which have required treatment in bed or operation. As a result of his study of this large number of cases Dr. Wilson has been able to bring together a very important series of conclusions. One of the most interesting questions in the treatment of acute pelvic inflammations due to puerperal infection is that of operative interference in these cases. The author unreservedly condemns the various radical operations which from time to time have been recommended. His own experience of removal of the uterine appendages with or without the uterus in six cases of recent puerperal septic and pyæmic conditions has not been such as to encourage him to add to it; for in none of the patients was death prevented, while in at least three it was hastened. In the case of complete disorganisation of the appendages the removal of the uterus by total abdominal hysterectomy is advised, and this operation is preferred to supravaginal amputation because of the lessened likelihood of necrosis of the tissues of the stump with the danger of infection of the cut surfaces and pus formation, and further because the removal of the cervix permits free drainage to be provided into the vagina where this is considered necessary. These lectures which contain a large amount of information collected by a careful and scientific observer are of much interest and should prove of value to all those concerned in the treatment of these common affections.

Catalogue of Lewis's Medical and Scientific Circulating Library, Including a Classified Index of Subjects. New edition. Revised to the end of 1907. Pp. 500. Price to subscribers 2*s.* net; to non-subscribers, 5*s.* net.—This book contains upwards of 9000 titles, with the year of publication and price of each book, and also a "subjects and authors" index containing 10,000 references, and will be found useful as a work of reference quite apart from Mr. Lewis's library. The work has been carefully done. Here and there, as must happen in a book compounded of special titles and proper names, a slip occurs, but in most instances where we tested a reference we found it correct and we can imagine that such a list of scientific books might be very valuable to many people. The fact that the library is charitably inclusive, so that in the list a good deal of obsolete and unimportant literature can be found, adds to the utility of the work, for it is exactly the obscure book which is hard to find.

Alimentation et Hygiène des Enfants. Par J. COMBY, Médecin de l'Hôpital des Enfants Malades. Third edition. Paris: Vigot Frères. 1908. Pp. xii.-532. Price 5 francs. —The aims which inspired Dr. Comby to produce this work were in his own words "to write on a new plan a little manual of the hygiene of infancy which everybody can consult with profit. It is addressed not only to mothers of families and those persons engaged in looking after children but also to medical men who do not always pay sufficient attention to the small details of the proper rearing of children." In furtherance of this plan the book is cast in dictionary form, so that a mother anxious for instruction upon "feeding, nurses, clothes, games, baths, schools," and so on, can turn up the necessary article easily without having to hunt it out amongst a mass of confusing information. In a work of this nature, with a double appeal to the public and the medical profession, there is an obvious danger of falling between two stools, but the author seems to us to have succeeded reasonably in his purpose. The section dealing with nourishment is the most important in the book and has been done with care and knowledge. We note a small slip in revision on page 80, where it is stated that "Budin donne également le lait pur," and so on—a sentence which unhappily should run, "Budin a donné." The language is clear and avoids all needless technicalities. There are some useful remarks upon education which deal with older children and a section on infant protection which proves that France is well aware of her responsibilities in that respect, as well she need be. The book deserves success.

The Vermiform Appendix and its Diseases. By DUNCAN MACARTNEY, M.A. Edin., M.D. Glasg., Surgeon to the Glasgow Cancer Hospital; Senior Assistant Surgeon to the Western Infirmary of Glasgow; late Examiner in Surgery to the University of St. Andrews. Glasgow: James Maclehose and Sons. 1908. Pp. 104. Price 3*s.* 6*d.* net.—The literature of the surgery of the appendix is so vast, and most of the works on the subject are so great, that it should prove convenient to many to have available a brief account of the subject. Dr. Macartney's book is on a very moderate scale; it deals very fairly with most of the diseases of the appendix but especially with appendicitis. The author is in favour of operating at once on every case of appendicitis; this practice, he tells us, follows logically from the fact that we have no certain knowledge of the condition of the appendix by the time that appendicitis has declared itself. This immediate operation in all cases does not commend itself to most surgeons and we see no likelihood of the general adoption of the practice. Dr. Macartney prefers Battle's incision and we agree with him that it is very good and simple and that it is very unlikely to be followed by a ventral hernia.

JOURNALS AND MAGAZINES.

Transactions of the American Otological Society. Fourteenth Annual Meeting. New Bedford, Massachusetts: Mercury Publishing Company. 1907.—Amongst the more important contributions to this volume are a series of papers on the Mastoid Operation, by Dr. William Bryant, Dr. E. A. Crockett, and Dr. James McKernon; a paper on Otitic Brain Abscess, by Dr. Dench; an Argument for Preliminary Ligation of the Internal Jugular Vein in the Treatment of Lateral Sinus Thrombosis, by Dr. Reich; a Case of Bilateral Thrombosis of the Sigmoid Sinus, with Recovery, by Dr. Grüning; Anatomical Considerations bearing on the Problem of Bone Perception, by Dr. Shambaugh; and a Case of Fatal Hæmorrhage from the Jugular Vein in Suppurative Otitis Media, by Dr. Jack and Dr. Verhoeff. All the papers in this volume are well up to the standard of excellence usually found in the work of this well-known society.

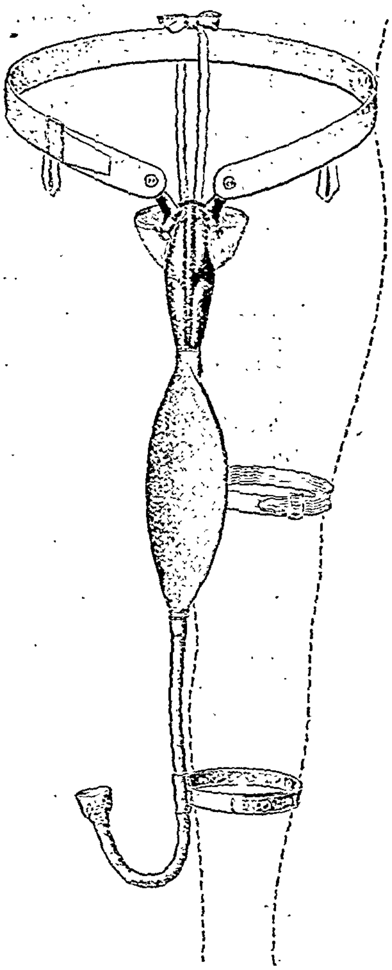
Zeitschrift für Laryngologie, Rhinologie, und ihre Grenzgebiete (Journal of Laryngology, Rhinology, and Allied Subjects). Würzburg: A. Stuber. 1908. Price 24 marks per annum.—This number contains the following articles:— Morphology and Terminology of the Middle Meatus, by Professor Heymann and Dr. Ritter. Angiomata of the Mouth, Naso-pharynx, and Larynx, by Dr. Voigt; this article is illustrated with a coloured plate, showing angiomata of the fauces and the larynx. Laryngeal Affections and Syringomyelia, by Dr. Iwanoff. The So-called Laryngitis Nodulosa, by Dr. Gerber. A Case of Congenital Air Cyst of the Larynx in a 16-day old Child, by Professor Kan. Congenital Membranous Webs in the Larynx, by Dr. Hamsberg. Amputation of the Epiglottis for Tuberculous Laryngitis, by Dr. Möller. Importance of Œsophagoscopy for the Diagnosis of Impacted Foreign Bodies, by Professor Starck. Neglect of an Important Operation for the Verification of Diagnosis, by Dr. Goris. Disturbances of Speech and Rhino-Laryngology, by Dr. Gutzmann. There is also a brief abstract of current literature followed by an abstract of meetings of societies.

Journal of Laryngology, Otology, and Rhinology for April and May.—The April number contains a report of several societies, with some reviews. The May number contains a brief obituary notice of Professor Schrötter and a paper entitled Contributions to the Surgical Treatment of Laryngeal Stenosis by Dr. E. von Navratil, with a Note on the Examination of the Nose by Dr. Mackenzie.

New Inventions.

A NEW PORTABLE URINAL.

WE have received from Messrs. Ellis, Son, and Paramore of Sheffield a sample of a urinal which they have recently designed for a customer, and as he has expressed high praise of its advantages over the style of urinal which he had been wearing previously they propose to put the instrument on the market. We have had trial made of the apparatus and think that it will be found to possess the advantages claimed for it. One innovation brought out by the illustration is that the hole at the top is so arranged that when the urinal is on the patient the instrument is very close fitting and there is no bulging outwards of the clothes, which is undoubtedly an unæsthetic feature of many portable urinals. The tubing at the bottom of the bag which passes down the leg is provided with a stopcock at the bottom so that the wearer may empty the vessel more conveniently than by lifting the bag from its position. This tubing is provided with a rubber leg band, keeping the pipe well under control when walking.



The urinal has been of course designed for both night and day use, but those who have to wear such apparatus know well that it is in the day-time that their inconveniences mostly arise. At night, in the privacy of their chambers, no further concealment is necessary, and it is not hard to devise an effective and cleanly form of portable urinal, but by day this is not so easy, and patients will be glad to provide themselves with an apparatus which will allow them to travel comfortably while keeping their infirmity hidden from the public gaze.

ILFORD X RAY PLATES.

WE have received further samples of x ray plates from Messrs. Ilford, Limited, of Ilford, London, E. We have subjected these to careful test in clinical work and are pleased to note that while retaining all the good qualities of which we spoke in a previous notice they have added that of greater rapidity to their other virtues. To attain this rapidity, however, it is necessary to use the developing formula given on the box, thus differing somewhat from ordinary photographic plates which give practically identical results with any standard developing solution. In our opinion the Ilford x ray plates are the best and the most rapid at present obtainable, and we may say that this opinion is not based on the use of these few samples but upon the employment of some thousands of these plates. Other things remaining the same, short exposures are the great desideratum in radiography, and so long as the modern x ray tube remains substantially in its present form it is to the photographic plate we must look to attain this end. On this account we hope that Messrs. Ilford, Limited, will not be content to rest on their oars but will strive, by means of further experiment and research, to obtain a still higher degree of rapidity. The makers are prepared to supply their emulsion coated on celluloid films of any size, such as are used in instantaneous radiography, on receiving a few days' notice.

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 3rd, 1830.

THE sufferings of GEORGE the FOURTH have terminated; his Majesty expired on Saturday morning last, soon after three o'clock. The sad intelligence was communicated on the same day to the Lord Mayor, in the following curious note from Sir Robert Peel:—

> "Whitehall, June 26th, 1830.
>
> "My Lord,—It is my most painful duty to inform you, that it has pleased Almighty God to release His Majesty from his sufferings. His Majesty died at about a quarter past three o'clock this morning.—I have the honour to be, my Lord, your lordship's obedient and faithful servant,
>
> "ROBERT PEEL."

The circumstances which have attended his Majesty's lamented illness, have been of so mysterious and extraordinary a character, the deception practised upon the public has been of so scandalous a nature, and the bulletins issued by the medical attendants have been so justly and severely reprobated, that we think it right to collect the whole of these documents, and place them in one view, before the eyes of this insulted community.

"Windsor Castle, April 15, 1830.

"We regret to state that the King has had a bilious attack, accompanied by an embarrassment in breathing. His Majesty, although free from fever, is languid and weak."

"April 19.—His Majesty continues to suffer occasionally from attacks of embarrassment in his breathing."

"April 22.—The King is better."

"April 24.—His Majesty has passed two good nights, and continues better."

"April 26, 9 o'clock A.M.—The state of the King's health continues much the same. His Majesty has had a good night."

"April 27, half past 10 A.M.—The King continued as well as his Majesty has been for several days past until this morning, when his Majesty experienced a return of the embarrassment of his breathing. His Majesty is now again better."

"April 28, 11 o'clock A.M.—The King has suffered less from the attacks of embarrassment in his breathing since our report of yesterday, and his Majesty has passed a good night."

"April 29.—The King continues much in the same state, with occasional embarrassment in his Majesty's breathing."

"April 30.—The King had several hours of refreshing sleep last night. His Majesty's symptoms are somewhat alleviated."

[Here follow daily bulletins from May 1st to June 19th, a period of seven weeks, which we have not the space to transcribe in our issue of July 4th, 1908, but proceed to transcribe the bulletins of the last seven days of the King's illness.]

"June 20.—The King's rest has been interrupted by cough, with expectoration during the night. His Majesty complains less, however, this morning."

"June 21.—The King's rest has again been broken by the cough and expectoration. His Majesty feels languid this morning."

"June 22.—The King has passed a good night. His Majesty's cough and expectoration continue."

"June 23.—The King is still troubled by his cough, but it has not interrupted his rest; and his Majesty awoke refreshed this morning."

"June 24.—The King's cough continues with considerable expectoration. His Majesty has slept at intervals in the night, but complains of great languor to-day."

"June 25.—The King has slept at intervals during the night, the cough and expectoration continue much the same, but his Majesty is more languid and weak."

"June 26.—It has pleased Almighty God to take from this world the King's most excellent Majesty. The King expired at a quarter past three o'clock this morning without pain."

[Here follow eight columns of observations and the official report of the morbid appearances which were observed at the post-mortem examination of the body of the King, signed by Sir Astley Paston Cooper.]

THE LANCET.

LONDON: SATURDAY, JULY 4, 1908.

Some Considerations as to the Metropolitan Aspects of the Housing Question.

THE discussion of the housing problem is becoming a sort of popular pastime and everyone, whether he has studied the problem or not, appears to have a panacea for it; some have several panaceas, as has been seen recently during the useful debates which have taken place at the Pan-Anglican Congress. The problem of housing some six millions of persons in such a fashion that each shall have a minimum of cubic space, of light, of relatively fresh air, and last, but in no sense least, of sex separation and privacy, ought not in the present temper of the public to be an insoluble one; indeed, it would seem that in some sort of sub-conscious fashion factors are at work which will eventually lead to the problem solving itself. But evolution on these lines will be halting, uncertain, and wasteful, and most of the adults upon the surface of this planet now will have sunk beneath it before much is accomplished. Still, it must be recognised that the flowing tide is with the housing reformer and that the growing desire for physical well-being, the limitation of the hours of labour, the development of electric traction, cheap fares, high London rates, and such like are all making for that residential exodus from the metropolis which is likely ere long to call for the application of the provisions of Mr. BURNS's Town-planning Bill in the counties immediately around London. But the housing of the London poor is by no means as bad as those who have seen nothing else would lead us to suppose. If a foreigner desired to see English housing at its worst he would not be shown the East-End of London but the slums of some of our provincial cities wherein is to be found row upon row of back-to-back houses in narrow, airless, lightless alleys, and where, in addition, he could study all the drawbacks of the conservancy method of excrement disposal. Or he might be taken to some of the mining districts of Durham or to famous Whitehaven to see the conditions which the abuses of building by-laws allowed to come into existence.

In so far as London is concerned, although we have made, and are making, progress, there is obviously much still to be done, and in an interesting report recently presented to he executive committee of the Mansion House Council on the Dwellings of the Poor by Dr. A. H. HOGARTH, its medical officer, and Mr. W. F. CRAIES, its architect, certain aspects of the problem are dealt with which are worthy of consideration. These gentlemen discuss the subject in some detail nd much of the material which they have brought together will be useful to other students of the problem. The inner, middle, and outer zones of the areas embraced by London proper and its surrounding districts as far out as Croydon on the south and Enfield on the north are dealt with separately, a map illustrating the several zones having been reproduced from the London County Council report on New Working-class Accommodation. As regards the inner zone, which comprises such districts as Bermondsey, Westminster, and Stepney, Dr. HOGARTH and Mr. CRAIES do not think that any extensive building schemes are, having regard to the cost of land, practicable, but they suggest that with a view of diminishing the overcrowding of persons in houses empty dwellings should be taken over, rendered habitable, and let in the form of tenements to families having at least two children at a weekly rental of not more than 2*s.* per room. It is contemplated that in this fashion it would be found possible to rehouse some of those persons now inhabiting insanitary houses and underground dwellings. Similarly with regard to the middle zone the writers deprecate any fresh building operations on a large scale, but they think that if any building is undertaken it should be mainly for the old-established poverty of Deptford, Greenwich, and Woolwich. For the rest they consider that the adaptation of empty houses in the sense suggested above, together with some redistribution of the existing population over the outer zone where good travelling facilities exist would be the best lines of attack. As regards the outer zone there would, they think, be much less difficulty in promoting new buildings, although at the present time the supply of buildings is in excess of the demand. The chief point in this outer zone is that future building should be carried out on some town-planning lines; that there should be a traffic board to arrange for travelling facilities and a committee to suggest schemes and generally to coördinate the various forces, organisations, and persons interested in this matter. What may perhaps be regarded as the special feature of the joint report is the suggestion, made, we believe, by Dr. J. F. J. SYKES some years ago in his Milroy lectures on the housing question, for the adaptation of existing empty houses into what would be technically regarded as houses let in lodgings. Dr. HOGARTH and his colleague show that schemes of this nature have been made financially profitable, while at the same time there is a distinct social and hygienic advance, not only in the dwellers in these tenements but by their influence upon the surrounding population. They also advocate improvement by the personal supervision of slum dwellers; indeed, all along the line they seem to contemplate, unconsciously perhaps, some sort of public-spirited policy on the part of the better classes as takes shape in Germany under the name of the Elberfeld system. Although possibly the proposals made in the report before us will not carry us a very long distance they are well worthy of consideration and, above all, of trial, and we quite agree with Dr. HOGARTH and Mr. CRAIES in advocating more coöperation between all existing organisations, municipal and philanthropic, as also in a proposal that there shall be a systematic development of new traffic routes and methods.

A much more drastic and direct proposal as regards the housing of London's population is made by Mr. F. B. BEHR in the June number of the *National Review*. In his opinion it is necessary in order to commence in an economical and thorough fashion to create fresh centres in places some 20 miles from London where land is relatively cheap and, recognising that in these circumstances existing modes of transit are useless if the first principle of new housing—that the worker shall not be more than an hour's journey from his work—is to be observed, he proceeds to develop new lines upon the Behr high-speed mono-rail system, by means of which a speed of 100 miles an hour can be attained without danger. The scheme is briefly this. There are three classes of people to be considered—day labourers, skilled workers, and clerks, groups which do not readily mix with one another. Mr. BEHR considers that by the removal of the second and third groups more room will be left for the first—the day labourers—whose circumstances of employment and remuneration necessitate their living near their work. Land is to be acquired at two centres: one 18 miles and the other 20 miles from London; in the first centre are to live the skilled workers, and in the second centre the clerks. Between 6 and 8 A.M. trains will run every two minutes from the 18-mile centre, and between 8 and 10 o'clock every two minutes from the 20-mile centre, there being another four hours of rapid train service to bring the people home in the evening. Each centre is to have a population, at first, of about 27,000, and to be arranged upon a definite plan with not more than 12 houses to the acre, and the cost of the whole undertaking has been worked out by Mr. BEHR in a fashion to yield well over 4 per cent. interest. He evidently thinks that philanthropy may reasonably be called upon to provide this capital, and, indeed, we rather gather that he has visions of a possible Government loan at some 3 per cent. interest. The proposal is by no means a visionary one and obviously the whole question of the population of London sleeping much beyond its present confines is merely a matter of rapidity and cheapness of transit. In the old coaching days the season ticket limits of to-day would have been impracticable, and if the economical aspects of the problem are to be guarded adequately some bold stroke, such as is here contemplated, is absolutely necessary. Some, however, will be inclined to ask, why not remove the industries from London as well, but this opens up a larger issue than we can conveniently deal with in this article.

First Aid.

IN THE LANCET of June 27th, p. 1857, reference was made to the successful efforts of the Viennese Street Ambulance Corps to meet the demand upon its services due to the recent jubilee pageant at Vienna. And now the serious and systematic manner in which ambulance service is being approached on the Continent is set before us in a volume containing a formal record of the first International First Aid and Life-saving Congress which was held during the early part of the summer at Frankfort-on-Main, embodied in the form of brief synopses of reports and papers laid before the Congress. Perusal of this volume arouses a feeling of admiration for the trouble which must have been taken by all concerned in order to insure a satisfactory exchange of opinions and experiences upon so important a subject and one of regret that England should not be represented in it by a larger number of useful papers on the important topics treated, such as those dealt with by three of our own countrymen whose names we observe. These are Mr. J. W. CROSTON who discussed the organisation and training necessary in order to enable railway companies to cope with their own needs for ambulance service and those of the country, whether in peace or war; Mr. S. OSBORN who took for his subject First-aid in London and the work of the St. John Ambulance Association; and Mr. HORACE FOLKER who gave information as to the work of the ambulance department of the National Fire Brigade Union, of which he is a vice-president. All these are important topics, for the study of which there is ample opportunity in this country, and we must express the hope that the inevitable difficulties surrounding attendance abroad on such an occasion may be overcome and that English experts may be found to come forward in a larger proportion than 3 to 77 of other nations, should the congress be repeated.

In considering the subjects discussed at the congress in question by foreigners of all nations we note that many of these would probably have been interested by an exposition of the methods adopted in England for the removal and isolation of cases of infectious disease. These with us are so completely under the control of legally constituted sanitary authorities that reference to them in pages chiefly devoted to the organisation of more or less voluntary ambulance work seems out of place. With regard to what may be called ambulance work pure and simple, arising, as it does, largely out of what we know as "accidents" in ordinary life or in the pursuit of some trade or industry, the field of discussion is a very large one and there should be room for a correspondingly important contribution of fact and opinion from our large labour centres and crowded cities. The essential difference between ambulance work in England and that on the continent can, however, readily be felt by those who read even the greatly condensed observations of German, French, and Russian authorities as indicated in the pages before us, a difference which must necessarily follow from conditions which to our neighbours are part of their ordinary life as citizens. Compulsory military service and the ever-present possibility of the employment of the country's army upon active military operations on a vast scale combine to train and to stimulate men engaged in peaceful occupations for duties and responsibilities which will have to be faced in earnest when war arises. To these the ambulance corps which deals with a mining or railway accident by means of its organisation and training is keeping itself in practice with a view to that work which is more essentially the service of the Red Cross, and which may at any time have to be done under the scanty protection afforded by that noble emblem. Quite possibly with the development of a new military system in England we may find that a fresh impetus has been given to a useful movement and that those who in the past have had the energy and public spirit to enrol themselves in the ambulance sections of our volunteer battalions or in the

St. John Ambulance Association will find their numbers augmented.

It is to be hoped that such will be the case, for the training is one of practical utility in whatever circumstances "first aid" may be required, and if ever what Mr. Kipling calls "the real thing" happens so as to affect our territorial forces directly, it will be too late to remedy deficiencies which in peace time we may have regarded with indifference. There is a branch of life-saving and first aid to which it is most appropriate to call attention at the present season. With the warm weather bathing becomes universal, and with the advent of the summer holidays drowning accidents figure very frequently in our newspapers. These, be it remembered, are the fatal cases as a rule, some of which might have been averted by means of a knowledge of how to aid a struggling swimmer or how to resuscitate the insensible body brought to shore apparently dead. The cases in which knowledge of how to save life has figured, particularly when it has been exhibited in the less heroic manner by treating the half-drowned person, are often not reported, and we would commend the first aid to be rendered in such cases to the attention of all.

◆

Improvement of Official Statistics.

Sir Charles Dilke in his address in November last, as President of the Royal Statistical Society, revived an important and interesting question which was considered and reported upon by the Official Statistics Committee appointed in 1877 by the late Mr. W. H. Smith when Secretary of the Treasury, the final report of which committee was issued in 1880. This report suggested the creation of a small central statistical department for the general supervision and control of official statistics, and Sir Charles Dilke in his address strongly urged the increased necessity, after the lapse of nearly 30 years, for action in this direction. At the last meeting of the Royal Statistical Society on May 16th Mr. Arthur L. Bowley, M.A., read a paper also dealing with the desirability of creating a central statistical authority in order to promote the improvement of official national statistics. In this paper, having regard to the object in view, it was perhaps natural that Mr. Bowley should have condemned somewhat too generally the value of the statistics issued by the various Government departments. The want, however, of uniformity and of general coördination in the statistics prepared and issued by different executive departments has long been generally admitted, although no measures have yet been adopted for carrying out this reform since the recommendation made in the report of the committee referred to. Sir Charles Dilke and Mr. Bowley give many striking examples of overlapping and even of contradiction in separately issued official statistics. M. Cheysson, an eminent French statistician, published in 1882 a report on the condition of Government statistics in various European countries, with a view to the creation of a general supervising and controlling authority in France, in order to bring about "harmony, proportion, order, and uniformity of arrangement in national statistics." As a result of this report a French Conseil Supérieur de Statistique, modelled on that of Belgium, was founded in 1885. M. Cheysson recommended in the first instance, and his advice was followed, coördination through a representative advisory committee in order to allay departmental suspicion and opposition. Sir Charles Dilke, however, in his address, expressed the opinion that "a mere meeting of statisticians from the various departments would be an insufficient result of our labours; a permanent statistical direction is, I think, required." It is obviously necessary, with a view to the improvement of official statistics, that the chief of the statistical branch of each Government department charged with the preparation of statistics should be a trained statistician. If this condition were fulfilled it would then become a question whether M. Cheysson's proposal for the creation of a consultative council, consisting of the chiefs of the statistical branches of the principal government departments, with, perhaps, one or two added unofficial statisticians, would not be preferable to the creation at present of the directing central statistical department recommended by Sir Charles Dilke. It certainly appears that to divorce the compilation of official statistics from the executive staff having the control of the collection of the statistical material would be a doubtful advantage and would involve some risk of deterioration in the result, since the true value of statistics depends much upon an accurate appreciation of the precise method of collection and of its various sources of possible error. We cannot, for instance, imagine that to transfer to a central statistical office the preparation of statistics of population, births, marriages, and deaths from the Registrar-General, who is the administrative chief of the large staff of outdoor officers who furnish the returns from which these statistics are compiled, would have any beneficial result. At the same time we wish every success to Sir Charles Dilke's desire for the creation of some central statistical authority with administrative or consultative power to promote greater uniformity and further improvement of our official statistics which are very generally admitted to be necessary.

Annotations.

"Ne quid nimis."

THE BIRTHDAY HONOURS.

In the long list of birthday honours published last week the following names of medical men occur:—Sir Thomas Lauder Brunton, LL.D. Aberd. and Edin., M.D. Edin., F.R.C.P. Lond., D.Sc. Edin., F.R.S., and Professor William Watson Cheyne, C.B., LL.D., M.B., C.M. Edin., F.R.C.S. Eng., D.Sc. Oxon., F.R.S., upon whom Baronetcies have been conferred; Brevet Colonel David Bruce, R.A.M.C., C.B., F.R.S., Mr. Robert William Burnet, M.D., C.M. Aberd., F.R.C.P. Lond., and Mr. Peter O'Connell, M.D., M.Ch. R.U.I., who have received the honour of Knighthood; William Henry Power, C.B., who has been promoted from a Companion of the Order of the Bath to be a Knight Commander of his Order; Lieutenant-Colonel Johnston Shearer, I.M.S., D.S.O., who has been made a Companion of the Bath, and Lieutenant-Colonel Francis Frederick Perry, I.M.S., honorary surgeon to the Viceroy, and principal of the Medical College, Lahore, who has been appointed a Companion of the Indian Empire. Sir Lauder Brunton, as our readers know, has made many valuable contributions to medical science and was our representative at the second Hyderabad Chloroform Commission and assisted to draw up the able report which was published in THE LANCET in 1890.[1] He was also a member of the commission which went to France to report on the treatment of hydrophobia by Pasteur's method. His "Handbook of Pharmacology, Materia Medica, and Therapeutics" is well known, as are also his "Disorders of Digestion, their Consequences and Treatment" and his "Collected Papers on Circulation and Respiration." Sir William Watson Cheyne, who was a consulting surgeon to the forces in South Africa during the late war, has been for many years in the van of scientific surgery. His Wightman lecture on the Defensive Arrangements of the Body, which we published in our last issue, is a thoughtful study of important problems the solution of which has a vital bearing on our medical and surgical procedure and well illustrates his manner of approaching surgical problems. He has contributed largely to professional literature, among his works being "Antiseptic Surgery: its Principles, Practice, History, and Results," and the "Manual of Surgical Treatment," written in conjunction with Mr. F. F. Burghard. Sir David Bruce, a member of the Army Medical Advisory Board, director of the Royal Society's Commission for the Investigation of Sleeping Sickness, and chairman of the Commission for the Investigation of Mediterranean Fever, is the well-known discoverer of the bacillus Melitensis, the immediate cause of Malta fever. His bacteriological investigations will long remain a monument to his patient research in the cause of sickness, especially in those diseases which so terribly handicap the white man in hot climates. His contributions to medical literature include "Malta Fever," "Nagana or Tsetse Fly Disease," and "Sleeping Sickness." Sir Robert W. Burnet, honorary physician to the Prince of Wales, was the friend of the late Prime Minister and was his medical attendant during his last illness. He is the author of several medical works. Sir Peter O'Connell is surgeon to the Mater Infirmorum Hospital and High Sheriff of Belfast. Sir William Henry Power, K.C.B., late medical officer to the Local Government Board and Crown nominee on the General Medical Council, is a member of the Royal Commission on Sewage Disposal. His investigations with regard to infectious diseases are well known and his position was admirably summed up by the late Sir Richard Thorne Thorne when he described him as "the greatest living epidemiologist." The nursing profession is represented in the birthday list of honours by the inclusion of the name of Miss Ethel J. Martin, matron of Queen Alexandra's Imperial Military Nursing Service, who has had conferred upon her the decoration of the Royal Red Cross.

SIR HENRY ALFRED PITMAN'S CENTENARY.

ON Wednesday, July 1st, Sir Henry Alfred Pitman reached the age of 100 years, having been born in 1808. Sir Henry Pitman's health is wonderfully maintained when his age is taken into consideration, while it is a sufficient testimonial to the working of his mental faculties when we mention that until the present year he has continued to act as auditor of THE LANCET Relief Fund. Among the many tokens of regard which Sir Henry Pitman has received there is one which we know that he will highly prize—viz., a handsome silver-gilt bowl, which was conveyed by a party of old friends and colleagues at the Royal College of Physicians of London, who proceeded to Enfield, where he resides, on July 1st, to felicitate him. Amongst these were Sir R. Douglas Powell, Sir Dyce Duckworth, Dr. G. Fielding Blandford, Sir William H. Allchin, Dr. Edward Liveing, Dr. C. Theodore Williams, and Dr. Frederick T. Roberts. The bowl bears the following inscription: "Presented to Sir Henry Alfred Pitman, July 1st, 1908, on the hundredth anniversary of his birth and in recognition of his long and valuable services as Registrar of the Royal College of Physicians." The Royal College of Surgeons of England has been no less prompt to recognise the occasion. From a letter sent to Sir Henry Pitman by the council of the College, and signed by Mr. Henry Morris, the President, and Mr. Rickman J. Godlee and Sir William Watson Cheyne, Vice-Presidents, we take the following passage:—

> We recall with satisfaction, and hold in great estimation, the valuable services, in the best interests of both medicine and surgery, rendered by you as registrar of the Royal College of Physicians, and as a member of the joint committees of the two Colleges; and the records of the Colleges bear witness to the energy and wisdom with which, throughout your tenure of office, you sought to foster and promote a high moral, social, and educational standard of the profession in this country.

A telegram of congratulation was received from the King, and an album of signatures from St. George's Hospital. We desire to associate ourselves with the numerous expressions of congratulation which Sir Henry Pitman has received. As a public servant and as a private friend he has been known to us personally for considerably over half a century, and we greet him on completing his hundredth year with every feeling of hearty and affectionate respect.

"SCOTT OF BROMLEY."

A CORRESPONDENT writes:—"Great reputations have a way of fading into obscurity with a rapidity not always deserved. No one now cites 'Scott of Bromley,' yet an obituary notice of him in Vol. II. of THE LANCET of 1848 speaks of his career as 'unparalleled in the annals of general practice.' The writer of 60 years ago is anxious that Scott should be remembered for all time, not only by the medical profession but by humanity at large. James Scott was a self-made man. He studied at the London Hospital, where he was a favourite with Blizard. Buying a small surgeon's practice at Bromley, which was worth £300 per annum, he soon raised its value to £1500 annually. He is said to have 'made it a constant rule to apply every dressing and perform every surgical manipulation himself.' He thus acquired a 'tactus eruditus' unrivalled at that time. He was a typical surgeon of his generation, bluff but kind, and inspired the greatest confidence in his many fashionable patients. Millar in the 'Principles of Surgery,' p. 375, says: 'Much credit is due to Mr. Scott for having directed attention to the importance of rest and pressure, combined with moderate irritation of the surface; and a modification of what is ordinarily termed "Scott's dressing" will be found a most valuable remedy in all chronic affections of joints.' His books on this and kindred subjects 'showed a profit of at least £10,000 a year for some years.' Truly, it would seem that, as THE LANCET biographer remarks, 'the lives of such men belong to all time.' The writer of the present note is reminded of James Scott—the magnificent mezzotint of whose portrait, engraved by C. Turner after Howard, R.A., is in its early state a collector's prize at this day—by finding the following account of one of his dressings in an old diary: 'I was under many surgeons—old John Scott in Broad Street, City, and after him his son [the diarist confuses father and son here]. Their way of treating it [a fractured periosteum of the tibia, originally doctored with "a bit of brown paper soaked in vinegar" in 1829!] caused horrible pain. It consisted in covering the place with a quantity of ointment and then strapping it up from the ankle to the knee—tight—with strips of diachylon plaster and a cotton bandage. This ate into the very flesh, and when I was wild with pain I passed an ivory knitting pin inside the plaster and drew it out covered with blood.' It should be borne in mind that this last was the desperate proceeding of a child under 15 years old. Callaway cut away the dressing and proceeded to new tortures with caustic, and partial relief was only found under Joseph Henry Green and Sir Benjamin Brodie, and later Rigaud in France, merciful men if any were. The whole thing happened a long time ago and the erewhile sufferer died at a very advanced age in 1905. The passage in the diary is only cited as proof of the painful and rudimentary practice of even famous surgeons before the days of Listerism."

---

THE TELEPHONE AND THE SPREAD OF DISEASE.

WE have received from the Post Office a copy of the report made by the City medical officer of health some three years ago upon the possible spread of infection by call-office telephones. It may be remembered that Dr. W. Collingridge examined a considerable number of call-office telephones and found them to be free from disease germs, but this fortunate fact does not minimise the importance of the report made in our columns last week by Dr. Francis J. Allan, medical officer of health of Westminster, who clearly showed that in certain cases call-office telephones may be a distinct source of danger to the public. It is quite true, as was stated on Monday last by the Postmaster-General in the House of Commons, that Dr. Allan found no trace of disease germs in five out of six call-office telephones which he tested, and it may be that the sixth instrument where a dangerous state of things was observed had particular features in its station to account for its condition, but it is impossible to minimise the fact that Dr. Allan has clearly proved that the call-office telephone may be a source of great danger.

THORACOSTOMY IN HEART DISEASE.

WE publish in another part of this issue of THE LANCET an interesting paper by Dr. Alexander Morison in which some observations are made concerning an operative method devised to afford relief to certain cases of enlarged heart. The enlarged area of pulsation and the forcible thrust against the chest wall in cases of greatly hypertrophied heart are familiar features in the clinical picture of certain forms of cardiac disease. Some years ago Dr. Morison suggested that the severing of pericardial adhesions by surgical methods might eventually be a practicable procedure, and again in a paper read before the Æsculapian Society and published in THE LANCET of July 28th, 1906, he suggested that the hypertrophied heart needed more room to work in and that it was possible that in the future a means might be found to provide such increased room by surgical methods. He now gives references to the actual carrying out of operations specially devised for this purpose with which he has recently become acquainted. He finds that as long ago as 1902 Professor Brauer proposed that the costopericardial adhesions in cases of adhesive pericarditis should be separated, and operations were carried out upon two of his cases by Professor Petersen and Dr. Simon, pieces of several ribs being resected in the first case, while in the second case a portion of the sternum was also removed. A third case was operated upon by Dr. Simon, and Dr. Morison is privately informed that a fourth case has been operated upon under Professor Brauer's supervision. Professor Wenckebach has also published a case in which parts of several ribs and their cartilages were removed. Dr. William Mackenzie of Melbourne has independently suggested the removal of portions of the sternum and ribs in order to free the heart from costopericardial adhesions. Still more recently Dr. Morison has developed the principle of affording relief to intrathoracic pressure by operative procedure by applying it to a case of mediastinal tumour involving the heart and to a case of cardiac pain associated with enlarged heart due to aortic valvular disease with a view to afford increased room independently of any question of relief of tethering due to pericardial and costopericardial adhesions. The clinical features of the latter case are described in detail in his paper. The patient was a clerk, aged 19 years, with aortic valvular disease associated with severe attacks of pain. After rest and medical treatment had failed to give relief Mr. Ewen C. Stabb, at Dr. Morison's suggestion, performed on May 1st an operation, removing four and a half inches of the fifth rib and five and a half inches of the sixth. The results of the operation to date appear to have been satisfactory and there has been considerable relief to the pain from which the patient suffered. It is obvious that the greatly hypertrophied heart has to make room for itself in the closed thoracic cavity and the bulging of the præcordia in children is an evidence of the force which it exerts upon the more easily yielding thorax in early life; consequently from a theoretical point of view the suggestion to afford increased room for the heart or to lessen the resistance which it has to contend against is one which has much to commend it. Practically, however, the procedure is a somewhat serious one to recommend to a patient with grave organic disease of the heart, involving as it does anæsthesia with a more or less extensive operation. Dr. Morison himself deprecates laying too great stress upon the result in a single case. Moreover, the time which has elapsed since the operation is very short. We shall await with interest the further progress of the case, and meanwhile we may congratulate Dr. Morison and Mr. Stabb upon the result so far obtained. We cannot but feel, however, that the cases submitted to this operation will require most careful selection, even should the permanent results prove as encouraging as those immediately obtained.

A "PSYCHIATRIC CLINIC" FOR THE JOHNS HOPKINS HOSPITAL.

Mr. Henry Phipps, who is a steel magnate of the United States, makes very good use of his fortune. He has founded model tenement houses in New York and endowed a special dispensary for pulmonary tuberculosis in connexion with the Johns Hopkins Hospital at Baltimore. That great centre of American medical research has benefited recently by a further gift of $750,000 from the same philanthropist for the purpose of founding a hospital for the treatment and study of acute mental disease such as Dr. Henry Maudsley's munificence has insured recently for London. The intentions of both benefactors are the same and were set forth in the leading article in which we discussed Dr. Maudsley's recent offer to the London County Council.[1] Mr. Phipps has made a study of the conditions under which the insane are treated in America and has concluded that the system is not worthy of his country; he is said to have been stimulated in his inquiry partly by the allegations made against it in that remarkable autobiography, "A Mind that Found Itself," which we discussed last week in these columns. Be that as it may, he has been convinced that a hospital is needed urgently in which sufferers from early mental disease can be treated on general hospital lines, without the stigma of undergoing certification or the distress of mixing with degraded dements. He wishes the institution to possess a thorough laboratory equipment and to afford every opportunity for the routine study of psychiatry by students of medicine. To these ends he will found a hospital for some 60 patients in the precincts of the Johns Hopkins Hospital and will provide for its upkeep, as well as for the maintenance of a professor of psychiatry, for a period of ten years. This professor will be the director of the hospital, and he will be assisted by a resident physician and two assistant physicians upon the clinical side, and by three physicians in charge of the pathological, chemical, and psychological laboratories upon the purely scientific side. The director, when he has been chosen, will visit Europe in company with the architect in order to study the construction and equipment of approved continental hospitals for the treatment of mental diseases. Mr. Phipps announced his splendid gift in a letter to Dr. W. H. Welch, who is credited with having aroused his interest and given him much expert advice in the matter. In the course of this letter he wrote: "It is my hope and expectation that the psychiatric clinic thus founded may serve as an example of what such institutions should be, and prove to be a stimulus to the establishment of similar hospitals and professorships elsewhere." Here is a plutocrat who brings a clear head as well as a singularly open hand to the bestowal of his charity. We congratulate Johns Hopkins University and Baltimore upon so important an addition to their scientific and humanitarian resources.

---

[1] THE LANCET, March 7th, 1903, p. 723.

DISEASES AND INJURIES OF THE ANCIENT EGYPTIANS.

MEDICAL men who are interested in the history of medicine will find an opportunity in connexion with the annual exhibition of preparations recently added to the Museum of the Royal College of Surgeons of England on July 2nd, 3rd, and 4th, of examining an extensive and remarkable series of specimens illustrating the diseases and injuries of the ancient inhabitants of Upper Egypt. It is not too much to say that this collection, which is destined to find an appropriate home in the Hunterian Museum, is one of the most important contributions ever made to the history of medicine. The specimens were collected during the exploration of some 57 cemeteries in Nubia, just beyond the confines of Upper Egypt, and represent accidents and diseases of every period of Egyptian history from early predynastic times to the comparatively recent Roman and early Christian periods. The collection, which embraces over a hundred specimens of healed fractures of various bones, was made by Dr. Wood Jones, under the direction of Professor G. Elliot Smith, during the survey necessitated by the projected raising of the level of the Aswan dam.

THE DIRTY CUFF.

FROM an æsthetic point of view the cuff seems to be an indispensable part of the clothing of the neatly and cleanly dressed individual. This assumes, of course, that the cuff is clean and spotless. Bacteriological refinements are often dismissed by many people as inadmissible in the common applications of life, but the exhibition of a dirty or even frayed cuff is commonly held to be the mark of slovenliness and dirt or as an indication that the individual has lost all regard for his cleanly appearance and condition. There can be no doubt at all that when the cuff picks up, as it is so prone to do, dirt from the counter, desk, or table it picks up also a multitude of micro-organisms. Dirt so far may be welcomed, inasmuch as it indicates an insanitary state of affairs. There is therefore a very strong scientific argument in favour of the wearing of materials which readily exhibit the signs of soiling. The white dress, the drills, and the ducks must necessarily be cleaned at regular intervals because they look unsightly or are an offence to the eye. The demand of the eye thus encourages the preservation of the hygienic state. It is so also with the cuff. No man with any respect for himself can wear a dirty cuff, and by keeping his cuffs religiously clean or by changing them frequently he is reducing his chances of coming into intimate contact with a collection of bacteriological entities. The adoption of "dark goods" or of those materials which do not show dirt may therefore be regarded as a retrograde step, for it is obvious that such materials must get soiled just as much as do those which easily show the defilement. They, however, are not so frequently cleansed because there is no offence to the eye even after several days' wear and thus dirt is allowed to accumulate. When a man finds it convenient to wear coloured shirts and cuffs he means in reality that he can carry dirt for a little longer without giving offence than if he wore a spotlessly white material, or at all events a material which readily exhibits the smear of dirt or grease. The washing bill is, of course, reduced and the terrors diminished of the disintegrating process which is involved in an oft-repeated visit to the laundry. Lastly, it may be mentioned that from the point of view of hygienic demand the coloured handkerchief is an abomination when its colour is merely adopted in order to avoid frequent washing.

IS BERI-BERI IDENTICAL WITH EPIDEMIC DROPSY?

DR. T. Frederick Pearse, the health officer of Calcutta, has lately brought forward weighty evidence in support of the theory that epidemic dropsy is identical with beri-beri. The former disease was observed first in the year 1877 in the southern suburbs of Calcutta, and appeared at intervals up to the year 1880, new localities being attacked with each recrudescence. 20 years then elapsed before the next outbreak occurred. The disease was at first thought to be of the same nature as beri-beri but was subsequently held to be distinct from it. Dr. Pearse has recently stated his views that the first impression of the nature of the disease is correct. He shows that the combination of symptoms in the two complaints is very similar. The greater or less œdema, especially in the shins, the hyperæsthesia and deep-seated pain in the legs, the cardiac symptoms, and the mode of death are common to both. The dropsy is shown in the same special and characteristic manner even to effusion in the pleural and pericardial sacs; also the nervous phenomena, if of less degree in epidemic dropsy, are identical in character—viz., those of peripheral neuritis. The conditions found post mortem are, although in no way characteristic of either disease, yet similar in both. As Dr. Pearse points out, the combination of œdema with symptoms pointing to peripheral neuritis with "rheumatic"-like pains and with disordered heart action, is only known in these two diseases. All the symptoms in the two diseases are similar in character, if not always in degree, and cases occur in outbreaks of each disease which are indistinguishable the one from the other. Finally, death is brought about in a similar manner, sometimes suddenly and sometimes slowly, by nervous disturbance of the heart's action. Reasoning on the above similarity in the course of the two affections, Dr. Pearse states his opinion to be that we have to look to some specific microbe as the cause of both. He certainly makes out a strong case in favour of his idea, as there are certain cardinal symptoms present in both affections—namely, the deep-seated pain and distinct tenderness of the calves, the great muscular weakness without absolute paralysis, the cardiac troubles as shown by shortness of breath, palpitation, reduplication of sounds, rapid and irregular pulse, and varying murmurs. Opponents of this view have pointed out that the knee reflex is lost in beri-beri but not in epidemic dropsy. This, however, is not universally true; in the recent outbreak at Calcutta of the latter disease the knee-jerk was either distinctly impaired or lost. Other writers, again, draw attention to the absence in beri-beri of the anæmia occurring in epidemic dropsy, but as Dr. Pearse points out, the blood conditions have not yet been sufficiently demonstrated to lay down any definite distinction between these two classes of cases.

THE STATUES ON THE NEW PREMISES OF THE BRITISH MEDICAL ASSOCIATION.

AT a meeting of the Council of the British Medical Association held on July 1st it was resolved "That, having carefully considered the objections raised and the many favourable expressions of opinion by eminent authorities on Art as to the statuary on the new premises, the Council instruct the architect to proceed with the work." We congratulate the Council on this decision. We fear that motives of advertisement may lead to some continuance of the so-called purity campaign, but the Council are so solidly backed by artistic opinion in the course which they are pursuing that they will not be much worried by such tactics.

THE ENTENTE CORDIALE MÉDICALE.

A NUMBER of the members of the Society of French Medical Practitioners who have been attending their recently concluded annual congress at Lille arrived on a visit to London upon Tuesday evening last. They are under the leadership of Professor Ambrose Monprofit, the distinguished surgeon of Angers, who was President of the French Surgical Congress of last year. The number of delegates and their wives who are visiting us is 344. This visit was arranged at very short notice and is not to be confused with that which is shortly to be made to London by another French medical party under the auspices of the "Voyages d'Études Médicales," and which we have already announced. In connexion with this latter visit Professor Landouzy, the Doyen of the Paris Faculty of Medicine, has promised to give a lecture in his own language at the rooms of the Royal Society of Medicine, 20, Hanover-square, at 5 P.M., on Tuesday, July 14th, upon Some French Health Resorts. Professor Landouzy has a great reputation amongst French medical orators and it is to be hoped that a large gathering of his English *confrères* will assemble to welcome him.

THE RELATION OF THE MEDICAL OFFICER OF HEALTH TO THE FEVER HOSPITAL.

THERE is a certain amount of difference of opinion amongst sanitary authorities as to what should be the precise position of the medical officer of health in connexion with the local isolation hospital, but it is, we think, very generally conceded that where practicable he should act as the medical officer, and where owing to the size of the hospital or the size of the district such a course is impracticable he should, nevertheless, exercise a general superintendence over the institution. As, however, will be seen by the account which we give elsewhere of a meeting of the Midland branch of the Incorporated Society of Medical Officers of Health, the Bilston urban district council has terminated, apparently in a very abrupt manner, the direct connexion of its medical officer of health, Dr. T. Ridley Bailey, with the isolation hospital. It is difficult to determine from the somewhat meagre account of the proceedings which has reached us what were the precise reasons for this remarkable line of action, more especially as there would appear to be no ground for complaint as to the manner in which Dr. Bailey has hitherto performed the duties appertaining to his office. We must confess that in so far as our own information goes we see no sufficient reason for the step which has been taken. Bilston has only a population of some 25,000 and doubtless Dr. Bailey is well able to devote the necessary time to his hospital duties. Moreover, we cannot but feel that a step such as this must have the undesirable effect of prejudicing the public against the medical officer of health, and having regard to the seriousness of such an apparently unjustifiable step as this it would, we think, be well if the Local Government Board were asked to hold a public inquiry into the matter through the agency of one of its medical inspectors. The local branch of the Society of Medical Officers of Health has unanimously passed a resolution strongly condemning the step taken by the district council and expressing the opinion that in the circumstances no medical man of any standing will be found to accept the vacant position. It is therefore clearly the duty of any self-respecting practitioner to communicate with the local branch of the society in question before applying for the post. Probably, however, a Local Government Board inquiry would be the best means of ascertaining all the facts and merits of the case.

THE TREATMENT OF TUBERCULOUS DISEASE BY TUBERCULIN.

WE have received a copy of a reprint of a paper published in the *Zeitschrift für Tuberculose*, Band XII., Heft 3, p. 216, 1908, by the late Dr. Augustus C. Kinney of Astoria, Oregon, U.S.A., on "Additional Observations of Remarkable Results from the Use of Immunity Treatment in Tuberculosis." The pamphlet is in substance a plea for the use of smaller doses of tuberculin. Dr. Kinney employed the watery extract of tubercle bacilli of van Rock and the antiphthisin of Klebs. He recommended injections once a month and later once in three months. He also employed the old tuberculin, which is sold under the name of tuberculinum Kochii. At first he used doses of 1/20th of a milligramme but subsequently he reduced them to 1/500th of a milligramme. The paper contains brief details of cases treated by these methods. They appear to be for the most part cases of advanced disease of the lungs and other organs. It is claimed that good results were obtained in a majority of these, excluding cases with mixed infections, though it is admitted that many cases were liable to relapse after recovery. It is therefore difficult, in view of the absence of details as to the number of cases treated and the duration of the beneficial effects obtained, to appraise properly the value of Dr. Kinney's results, but his views as to the advantage of smaller doses are in accord with those advocated by Sir A. E. Wright and the general tendency is nowadays in favour of even smaller doses than those recommended by Dr. Kinney.

CANCER OF THE WOMB.

AT the request of the Central Midwives Board Dr. F. H. Champneys has, as we announced last week, drawn up a circular letter for the information of certified midwives in which is urged how extremely important it is that any woman who is suffering from symptoms suggesting the onset of cancer of the uterus should seek medical advice at once. In the circular great stress is laid on the fact that no time should be lost in such cases, and on the further fact that the change of life should not be accompanied by floodings, irregular bleedings, or irregular discharge of any kind from the womb. The chief complaint of all surgeons is that they see cancer cases too late because the patient has ignored symptoms which may have been present for some weeks or even months. The remedy for this unfortunate state of things is to be found in the better education of women with regard to the great importance of seeking medical advice when any such symptoms are present. Unhappily it is usually the neglect of the patient to take heed of what only too often she regards as a discharge of no moment that prevents her medical attendant from having an opportunity of recognising the presence of cancer of the uterus sufficiently early to enable it to be removed with any great prospect of success. We are glad to see that the Central Midwives Board is taking the matter up, as it is only in some such manner that the great mass of women can become instructed in this most vitally important matter. The results in Germany of an active campaign started by Professor Winter are extremely encouraging and the percentage rate of operability of these cases has steadily increased during the last five years and is still rising. The preparation and issue of such a leaflet have been suggested by many gynæcologists in this country and we do not think that any harm is likely to result from it. Possibly the information which it contains may lead some women to think that they have cancer when such is not the case, but if it is successful in causing any woman with suspicious symptoms to seek medical advice at once it will result undoubtedly in increasing the number of cases in which a radical operation is possible and so will procure the saving of many lives.

THE ROYAL DENTAL HOSPITAL OF LONDON.

Sir Frederick Treves, Bart., G.C.V.O., C.B., occupied the chair on the occasion of the jubilee festival dinner of the Royal Dental Hospital of London which was held at the Hotel Cecil on June 25th. In proposing the toast of "The Hospital and School" the chairman made a powerful appeal to those gathered around him for a strong and united effort to place the funds of the hospital on a satisfactory basis. He pointed out the peculiar position occupied by the hospital in regard to public opinion. The hospital, he thought, was not appreciated as it ought to be and some people pretended that they could not understand why £47,000 should be required for a dental hospital when teeth could be pulled out in the street. Dental operations very commonly formed the basis of caricature and few seemed to realise that dentistry had developed along lines which involved many marvels of applied science. He had visited the hospital on more than one occasion and with the result always that he came away with a feeling of admiration for the skill of the staff and for the splendid equipment and accommodation which the hospital afforded to suffering humanity. England, he added, could be proud of its magnificent charity to hospitals, and beneath that charity there was a spring of sentiment which, however, and unfortunately, did not touch a dental hospital where there were no beds and no patients to whom kindly gifts could be brought. Surgeon-General Sir Alfred H. Keogh, in replying to the toast of "The Imperial Forces," referred to the great progress which was being made in regard to dental treatment in the army, and said that for years past they had rejected as unfit for the army a number of young men who but for dental defects would have been capable of service. The subject was receiving the attention also of our naval authorities, to which allusion was made by Inspector-General James Porter in his reply to the same toast. It was announced by the chairman on giving the toast of "The King," that His Majesty had headed the subscription list with £50, and during the evening the donations promised amounted to £3000. The toast of "The Visitors" was proposed by Sir Richard Douglas Powell and was responded to by Sir James Crichton-Browne. An excellent programme of music by the "Westminster Singers" added to the enjoyment of the evening. The proceedings were altogether successful and great credit is due to those who shared the work of organisation.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

King Edward's Hospital Fund has recently issued a circular to the hospitals of London reminding them of the resolution sanctioned by the General Council in 1903 to the effect—

> That in future any new hospital or those reconstructing or extending to a considerable extent, within the area dealt with by the Fund, be requested before taking definite action to submit their proposals to the Fund.

The circular proceeds to set forth the full purport and intention of this resolution and among other points states that the information submitted to the Fund should include the following:—

(1) Reasons and considerations which have led to the formulation of the proposals.

(2) The nature of the proposals, with any outline sketch which may be necessary in order to make clear the main features of the site and buildings, but not detailed architects' plans unless specially asked for.

(3) The amount of accommodation proposed to be provided, or other increase or modification of the work of the institution; compared so far as may be necessary with particulars of the present work.

(4) The rental and tenure of the site or buildings.

(5) The estimated cost of the proposals.

(6) The resources from which it is anticipated the cost may be met.

(7) The prospect of the provision for the increase (if any) in the cost of maintenance.

(8) The approximate dates of the beginning and completion of the work.

Similar information is requested from the promoters of new hospitals who might contemplate an application to the Fund in the future. But it is pointed out that the Fund does not assist in the foundation of new hospitals or entertain applications for grants from hospitals that have not been in existence in a properly constituted form for a period of at least three years. The King Edward's Hospital Fund is an institution which exists for objects which can only excite admiration, and its administration in the main has proceeded on sound and judicial lines. It may concern itself perfectly legitimately with checking wild and reckless schemes for extending hospital premises which take no heed of the probabilities of the income for their maintenance being found; but there are various ways of exercising such control and the tone of this circular may, perhaps, be regarded as unnecessarily peremptory.

TREATMENT OF NEURALGIA BY SUBCUTANEOUS INJECTION OF CHLOROFORM.

IN the *New York Medical Journal* of June 13th Dr. S. O. Goldan has reported very successful results in the treatment of neuralgia from an old method which has fallen into disuse—the subcutaneous injection of chloroform. He does not recommend it in acute neuralgia, in which medical treatment is usually effective, but in those chronic cases in which all palliative methods have failed and the patient is willing to submit to anything. From two to ten minims of pure chloroform are injected into the painful area with an ordinary hypodermic syringe. Considerable swelling and redness are produced which may seem alarming, and some patients will not submit to the treatment. Dr. Goldan has treated seven cases of facial neuralgia; in three the supraorbital nerve was affected, in one the infraorbital nerve, and in three the infraorbital and maxillary branches combined. The treatment instantly caused almost complete cessation of the pain. One patient had been treated previously by injections of osmic acid. From two to five drops of chloroform were injected in five or six places about one-half to one inch apart on the painful area. Three cases of brachial neuralgia were treated successfully by fairly deep as well as superficial injections. In seven cases of intercostal neuralgia immediate relief was given. The injections were made into the skin as well as deeply between the ribs. Five cases of sciatica were treated; in three repeated injections were required but the patients were completely cured. One patient, though benefited, refused further injections. One patient was not benefited and, indeed, was temporarily made worse, but in this case there was not merely sciatica but also phlebitis involving both limbs as well as the veins of the pelvis. The sciatica was greatly improved as a result of improvement of the phlebitis, which took place under treatment with the waters of Bagnoles de l'Orne, France. Dr. Goldan has also obtained good results from this treatment in lumbago. Patients have come to him almost creeping and within half an hour have walked away free from pain and erect. He ascribes the benefit to the inflammatory reaction produced by chloroform, which determines a new supply of blood to the nerve filaments of the painful part. Neuralgia, it may be remembered, has been described as the cry of the nerves for blood.

NATIONAL TUBERCULOSIS CONFERENCE AND EXHIBITION.

WE may remind our readers that a National Tuberculosis Conference and Exhibition will be held in the Caxton Hall, London, during November next. The conference is not a medical one but a national one, in accordance with its title, and its object is to arouse all sections of the community to the importance of securing more adequate means for the prevention and treatment of tuberculosis in all its forms. Consumption is a national scourge, calling for effective organisation and for the practical coöperation of all scientific, educational, and humanitarian forces which make for human betterment and racial progress. As is well known to all our readers, a series of very successful conferences and exhibitions has been held recently in different parts of Ireland under Viceregal patronage. These meetings have excited wide interest and greatly stimulated the anti-tuberculosis movement in Ireland, and it has been considered highly desirable that a thoroughly representative conference should be held this year in the capital of the British Empire, and the formation of a scientific exhibition is part of the scheme. The enterprise should appeal to all interested in and working for the physical improvement of the nation. It is arranged already that during the conference authorities from different parts of the Empire as well as continental leaders in the anti-tuberculosis movement shall take part in the proceedings, and arrangements will be made for country and foreign visitors to visit the chief sanatoriums and special hospitals for consumptives and other sufferers from tuberculosis situated in and near London. No efforts will be spared to interest all sections of the community in a consideration of the fundamental principles and scientific procedures on which the conduct of a successful campaign against tuberculosis must depend. It is hoped that all in any way interested in the objects and work thus outlined will communicate with the secretaries to the organising committee, Mr. Frederick V. Fisher and Mr. Ernest Schofield, at the offices of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., from whom all particulars can be obtained.

THE annual general meeting of the Coal Smoke Abatement Society will take place to-day (Friday) at 3 P.M., at the Royal United Service Institution, Whitehall, S.W. The President, Sir William Richmond, K.C.B., R.A., will occupy the chair.

EXETER SEWAGE WORKS.—A Local Government Board inquiry was held at Exeter on June 23rd into the application of the Exeter city council for sanction to borrow £1272 for improvements at the Exeter sewage disposal works. It will be remembered that Exeter was a pioneer town in the adoption of the biological method of sewage disposal.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

IT is undoubtedly true that one's first car is usually, and rightly, a small one; mine, bought some ten years ago, was a 3-h.p. Benz. Unfortunately many, like myself, I think, do not realise that later a larger car may be, and probably will be, bought, so at the beginning a small motor-house is put up and then when a new car comes there is the worry of altering it. And that is not only a worry but also an expense. I have been through it, so I speak from experience. So if I may advise the embryo motorist I would suggest, when you invest in your first car certainly let it be a small one but do not be too parsimonious over its house. A good many medical friends have asked me about the kind of shed which they should erect for their automobile. Well, I do not think that a medico is likely to indulge in any machine longer than 13 feet or wider than 5 feet 3 inches, or higher than 7 feet, so a building that will accommodate one of these dimensions should do. Of course, wooden sheds which are moveable and come in segments can be purchased; still the insurance companies are rather shy about having timber structures near one's house, so where a man is in practice and likely to remain for some time I strongly advise a permanent brick building. The accompanying plans are based on how I should build my motor-house if I had my time over again, and taking the cube at 6*d.* such a shed as I propose to outline could be put up for £40, and, what is more, there would be room to carry out repairs in it, and, of course, if electricity be available it could be lighted and heated in that way. Electricity is, I understand, sold at a very low rate for heating, and if it be used the accumulators could, by means of a suitable switch, be charged while the lamps or fire are on without extra cost, and accumulators do have a longer life if they are kept fully charged and are not allowed to run down. Of course, in modern cars magneto ignition is the rule; still, a dual one is especially desirable for a medical man and a high tension coil and accumulator should be the stand by, in addition to the high or low tension magneto. But to return to the house. I suggest one 16 to 18 feet long, 10 to 12 feet wide, and 8 feet high at one end and 10 feet at the other; the roof will thus have a good fall and can be made of corrugated galvanised iron. Steel revolving shutters make an excellent door and have the advantage of not occupying much room; sliding doors can also be employed or ordinary folding ones, but the revolving shutters seem to me the most ideal. I believe, as it is a mere shelter house, that the surveyor will allow a 9-inch wall, and those who do not mind expense can, of course, use glazed bricks (they look much better), but unfaced whitewashed ones will answer. A nice refinement is to have a coved brick at the junction of the wall with the floor and to have all angles rounded, as is done in modern operating theatres. The width I give will permit of getting round the car and allow of tyres being changed in the shed, springs seen to, &c.

A pit is most useful and I always regret that when I built my shed I did not make mine as long as I might have. It should be in the centre of the floor, 3 feet 6 inches wide, and at least 10 feet long; the floor of the pit and house should be concreted or covered with flags of artificial stone resting on concrete and should have a slight fall, about a quarter of an inch to the foot, and the pit should be drained, if possible into the manhole that leads to the sewer, the usual S-trap being interposed; the fall of the floor of the shed itself will permit of its drain being outside and in front of the shed door. Where it is not convenient to run the pit drain into a sewer a hole deeper than the pit can be dug outside (at the back) of the shed, filled in with broken bottles and bricks, and a pipe from the pit can open into it at a lower level than the floor of the pit. The pit should be surrounded by a curb, standing up some 2 inches and covered by hatches, each about 2 feet wide, so in working under the car that portion of the pit which is under the actual work may be open and the rest kept covered. A convenient depth for a pit is from 3 feet 6 inches to 4 feet, and steps can be made at one end so as to enter with comfort, though, as a rule, mere iron rings are fixed in the wall for purposes of access. It is handy to fit in the walls of the pit little recesses all the way round, so that when working they answer as shelves on which to place the tools that may be needed.

At the further end of the shed a window almost the width of the shed can be made, some 6 feet above the ground; four small windows, as shown, will probably be cheaper than one large one. At the back above the windows provision should be made for a countershaft, to have bearings on each side of the shed, and these bearings should have little tin trays hanging under them so as to prevent oil dripping down and making a mess on the floor, which in addition is unhealthy for the tyres. The countershaft can be run by a small electric motor, which can thus drive a small Drummond lathe, a most useful aid to small repairs, and the working of which will, I am sure, prove a fascinating amusement as well as a great saving in the repair bill. The lathe can be placed at the left of the back of the shed, and on the right a bench should be made, one 4 feet long and 3 feet high and 18 inches wide, with the top of inch material; will do, 2-inch square stuff being used for the supports. To the table a good-sized vice should be fixed. Parkinson's Perfect No. 7 or 8 with a width of jaw of some 4 to 5 inches is an excellent one. Under the bench the electric motor can be put and over the bench a rack for tools and a shelf for spares.

DRAWING FOR A MOTOR SHED.

Unless the water in the radiators is run out at night time the shed must in winter be warmed; an electric radiator answers well and is inexpensive to run, though the initial cost is high. If electricity is not available, then hot-water pipes, with the stove outside the shed, is the best method of heating. It is important that the stove should be quite away from the shed, as petrol may always escape or leak, and of course the vapour is most explosive. Fletchers make a little stove well fitted to keep water-pipes hot. Electricity is the ideal artificial light; failing this lamps must be fixed outside the house and their light admitted through windows. In front of the shed it is desirable, if possible, to have a yard paved and drained where the car can be washed. Petrol should not be kept in the shed but in two-gallon cans at some distance off. Personally, I do not keep more than what is in the car's tank, which my lad fills up while on my round. Spare tyres and tubes are best in a dark cupboard, and they are all the better for a little damp.

A good many motorists complain that their carburettors leave much to be desired, especially in regard to petrol consumption. Frequently this is more the fault of the car owner than the vapour-producing and mixing apparatus. A carburettor with a punctured float will often work if there is an overflow hole through which the excess of petrol can escape, but even then the mixture may be too rich and overheating of the engine thus takes place as well as extra trade for the petrol seller, and though the fluid is now but 1*s.* a gallon still there is no object in getting an extra quantity, for the sprinkling of the ground is of use to no one except perhaps the man who sells petroleum spirit. For those contemplating a change I can strongly recommend a new type of a mechanical automatic carburettor which is introduced by Messrs. H. M. Hobson, Limited, of 29, Vauxhall Bridge-road, London, S.W. It is the Claudel-Hobson. The whole carburettor, float chamber, mixing compartment, petrol channels, and the hot-air or water jacketing is in one casting. A fine sieve clears the petrol of any possible impurities prior to its admission to the float chamber, and on its further progress to the jet it is heated by either hot water or air, the latter from the exhaust. Some friends who have a carburettor which is heated by a hot-water jacket tell me in winter (their coach-house is not heated) that they have had trouble through the water in the jacket not draining all away and the part remaining behind freezing. In this carburettor exhaust pressure heating can be employed instead of water—an advantage to those with non-heated stables and who in winter drain off their water when the thermometer is near freezing. The jet is fitted with an air injector, and this and the way in which the throttle and control are cut and combined with the air regulator constitute the special features of the invention. The jet is covered by a tube, drilled at the bottom with holes and also at the top at the same level as the jet. When the throttle is shut the top part of the jet is in the mixing chamber, and the petrol is sucked through the top holes of the tube, whilst the suction is relieved by a proportionate quantity of air entering through the holes of the bottom of the jacketing tube, which is in direct communication with the atmosphere outside the regulator, thus insuring a perfect spray and an accurate proportion of petrol passing into the mixing chamber, whilst the throttle and air strangler combined are so cut that when opened—to whatever extent—for the engine to pick up, accurate proportions of air and petrol pass into the cylinders. Messrs. Hobson seem so certain of the petrol-saving advantages of their speciality that, I understand, they are willing to fit one of their carburettors for any owner afflicted with an extravagant one, and if it does not result in a considerable saving without any loss of power they will replace the old carburettor without making any charge whatever.

In most cars a small filter is introduced where the petrol supply pipe is connected to the float chamber, and as blockage of the jet is a bit of bother it is as well, where there is no such filter, to slip in under the pipe union a small gauze strainer washer and to recollect occasionally to clean it. A tool that should always be carried is a box spanner that will fit the jet; it is so annoying to diagnose a foreign body there and not be able to take it out for cleaning. It is seldom any good to introduce a bonnet pin into the top of the jet, for though the obstruction may be moved as soon as the engine starts it is drawn up into the narrower part, where it probably once more lodges and thus starves the engine. Occasionally the offending matter may be sucked through by putting some petrol into the cylinders through the compression taps and starting and racing the engine. Breakage of the petrol supply pipe is serious, and in addition to the loss of the petrol and its consequent ignoring of its proper destination, the engine, if it escapes near the hot exhaust pipe, may catch fire. A temporary road-side pipe repair can be carried out by cutting out the defective part and joining the divided ends by a bit of rubber tubing and affixing each end to the tube by a turn of copper wire. A cracked pipe can be made to answer for a time by binding it round and round with a soaped bandage and twisting over this some adhesive strapping. I did this once with some ordinary antiseptic adhesive plaster and it carried me for a whole morning's round. Occasionally the diagnosis of erratic running of the engine is a source of perplexity. Ignition causes being eliminated, the thought of "too weak a mixture" suggests itself, but the jet is clear, the petrol supply-pipe is found to be free. Then it is as well to inspect the joints where the induction pipe joins the mixing chamber or where it is attached to the inlet valve dome; a leaky joint at either of these parts may cause a weak mixture and account for the trouble. A little oil placed round the joints when the engine is running will by bubbles reveal if they are defective. A little asbestos cardboard rubbed over with red lead will remedy the complaint.

The Stepney Spare Motor Wheel Co., Limited, of Llanelly, who are the inventors and makers of the well-known and certainly most useful Stepney wheel, have put on the market an accessory that not only facilitates the fitting of their speciality but also extends its value by arranging it as a non-skid. Hitherto it has been necessary to push the outer covers inwards in order to fix the hooks of the Stepney wheel to the rim of the damaged car wheel. The new flange obviates this. It consists of a ring, which by means of bolts and nuts is fixed through the felloe, and not only improves the appearance of the car wheels but also strengthens them and makes it possible to fit the Stepney wheel not only in much less time but also with much less trouble, and if a non-skid studded tyre be on the Stepney, if rain comes on and the road becomes skiddy, a non-skid can be placed in position in a few seconds, and can be employed only when it is needed. This seems a very great advantage, for non-skids certainly wear more rapidly than plain tyres and are not always wanted, and with the new Stepney flange they need only be used when they are required. The company has opened show-rooms at 168, Great Portland-street, where those who are interested can see the flange. I was so impressed with the advantages of this new flange that, though I had merely visited their *depôt* for the purposes of this article, I ordered a set and they were very quickly fitted—in fact, I left the car at their place, and when I came back in one and a half hours the flanges were on and the car was ready.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are some of the principal amounts, additional to those already announced in THE LANCET, received at the Mansion House up to Tuesday evening, when the sum paid in was about £20,000:—

SOME ORIENTAL SUPERSTITIONS IN MATTERS OF THE HEALING ART.

AN interesting lecture delivered recently by Dr. David Sandler at the residence of the American Consul-General in Constantinople dealt with the Oriental superstitions which are met with constantly by medical men *practising* in the Near East and which frequently result in serious consequences to persons suffering from *injury or disease* who are "treated" by "magical" methods as the result of such beliefs. Dr. Sandler considers that the Oriental mind is so attracted by the supernatural that it is unable to widen the spiritual horizon and to look for natural and reasonable interpretations of material phenomena. It is a mind completely unable to grasp the orderly sequence of cause and effect which is the basis of all scientific conceptions. Untrained and uninitiated into such methods of *rational* associations, it pins its faith, oftentimes uncommonly strong and fierce in all its crude savagery, to primitive incongruities of belief and magical formulæ. It would almost seem that the more incongruous and incomprehensible a belief may be the more chance it has to lodge itself definitely in the Oriental mind as completely rational and worthy of the highest respect. Nowhere is this fact more clearly apparent than in matters of the healing art. Dr. Sandler gave a simple illustration. A stone strikes some part of the body of an Oriental and inflicts a wound. The train of ideas that this accident would produce in his mind would run something like this: The stone is the cause of pain, the cause of the wound. It is the principal origin of the trouble. But the essence of every origin is hidden, secret and therefore sacred. The stone becomes an awe-inspiring fetish. The wound is neglected. The fetish has to be propitiated. This simple illustration is borne out and supported by every-day experiences which medical men encounter in the East. Another instance may be derived from amongst the lower classes of the Greek population of Constantinople. A child falls and cuts his head. The first thought of the parent is to be sure not to wash and to bind up the wound, still less to call medical assistance, however grave the cut may turn out to be. This is always an after-thought, which very often comes so late that the help of a surgeon can prove of no use. The first thing the father or mother of the injured child thinks of doing is to pour over the shoulder upon the place of the accident a libation of wine or sugared water and to whisper, in performing this, some mysterious formula of incantation, an ancestral formula supposed to possess supernatural efficacy against every form of evil.

The Moslems are addicted to the queerest practices for purposes of healing or alleviating bodily pain. A Turk, for instance, in distress or suffering from some disease, however severe, knows of no better remedy than to fix a piece of his dress, torn off with true Oriental equanimity, to an iron bar of some saint's tomb, or to drink water from a tumbler into which he has previously put a sheet of paper with writings from the Koran. Sometimes he will take a jar, the interior of which has been written all over with strange formulæ and signs. He will then fill it with water, wait till these formulæ and signs have been thoroughly dissolved, and drink the singular solution with an absolute faith in its wonder-working efficacy. Sheltered by the sombre cypresses of the great Mahomedan cemetery at Scutari (the ancient Chrysopolis on the Asiatic coast of the Bosphorus) there stands in picturesque solitude the tomb of a horse. Every Friday afternoon Turkish mothers carry to that tomb their crippled children to be submitted by a select "khodja" (priest) to an extraordinary course of treatment. These children are dragged, with their diseased limbs dangling over the hillock, from one end of the tomb to the other and then back again in the same fashion. The occult influence emanating from this hillock is supposed to be an all-efficient panacea. It is not difficult to trace in this case the crude, imperfect association of ideas. The horse has long been considered an emblem of vigour, typifying, as Ruskin says, "the flow and force of life." Hence the belief of the Oriental, inherited, no doubt, from the Greeks, in the all-conquering virtue and influence of occult and mysterious effluvia which are supposed to emanate constantly from a horse's tomb.

The wearing of a necklace of blue beads or of garlic as a potent means of keeping away disease or of warding off the evil eye is quite a universal matter of sincere belief in the whole of Turkey. This superstition is shared, as is well known, by the lower classes of many a country in civilised Western Europe. There, however, it is not so universal and flagrant as in the Orient. There is scarcely a house in the Moslem, Greek, and Armenian districts of the population of Constantinople which has not hanging above its entrance door a collection of garlic, and scarcely a beast of toil which has not attached to some part of it a string of blue beads. Among the uneducated it is impossible to find an individual who does not pin his absolute faith to the all-healing power of such charms, especially of blue beads, which are supposed to be an unfailing panacea against every possible ill. Less general is the belief in the East in the baleful influence of the planets Saturn and Mars upon the constitution of the human body, upon its *four cardinal* humours, blood, phlegm, yellow bile, and black bile. These planets are considered by *some Orientals*, especially in the far South, as the unmistakeable causes of all sorts of ailments. Woe is unto him who begins any work when Saturn or Mars is in the ascendant.

Among the terrible practices by means of which diseases, such as pneumonia or diphtheria, are believed by the Oriental *to yield* unvaryingly is the application of a red-hot iron to the abdomen of the bed-ridden patient. By this means "the beastly influence," which is supposed to have settled in the diseased person, is expected to be expelled. On one or two occasions Dr. Sandler has seen traces of this barbarous mode of treatment on the bodies of helpless children of a very tender age. Should the unhappy martyr be brought by such ruthless artifice to the brink of death no better remedy is known of than to send speedily for a priest who is expected, for a consideration, of course, to cure the patient by mysterious and meaningless invocations.

Thaumaturgy has a potent influence with the Oriental's disposition; he therefore despises simplicity and gives credit and preference to the mysterious and the complex. Give him a colourless and tasteless medicine and his faith in it, as well as his confidence in the medical man, will at once be shaken. "It is too plain, too artless to be of any use," he will think. But let the prescription be several inches long; let it include a dozen, or even more, of different substances; let these substances be as rare as possible, as bitter or acrid as possible, or even as disgusting as possible, and the Oriental will take them with fullest confidence and think wonders of the physician's skill and learning. He has, in fact, the same notions of the practice of medicine as were held universally by Europeans in the Middle Ages, lingered on amongst the educated classes into the seventeenth and even the eighteenth centuries, and in an attenuated and shamefaced form have not yet entirely died out, as witness the ancient practice of wearing amulets which was revived in this country some few years ago for the relief of rheumatism.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest towns 8820 births and 3664 deaths were registered during the week ending June 27th. The annual rate of mortality in these towns, which had declined in the eight preceding weeks from 15·7 to 11·6 per 1000, rose again to 11·8 in the week under notice. During the 13 weeks of the past quarter the annual death-rate in these towns averaged only 13·8 per 1000, and in London during the same period the rate did not exceed 13·3. The lowest annual death-rates in the 76 towns during the week under notice were 5·2 in Walthamstow, 6·1 in Handsworth and in Newport (Mon.), and 6·6 in Tynemouth; the rates in the other towns ranged upwards, however, to 19·8 in Wigan, 20·6 in St. Helens, 21·6 in Stockton-on-Tees, and 24·5 in Hanley. The death-rate in London during the week did not exceed 10·8. The 3664 deaths in the 76 towns during the week showed an increase of but 42 upon the low number in the previous week, and included but 296 deaths which were referred to the principal epidemic diseases, a lower number than in any previous week of this year; of these 296 deaths, 82 resulted from measles, 73 from whooping-cough, 70 from diarrhœa, 35 from diphtheria, 21 from scarlet fever, and 15 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases last week were equal to a mean annual rate of but 1·0 per 1000, corresponding with the low rate from the same diseases in each of the two preceding weeks; the rate from these diseases in London was again so low as 0·8. No death from any of these epidemic diseases was registered last week in Oldham, Walthamstow, Plymouth, Halifax, and in 12 other smaller towns; the annual death-rate from these diseases ranged upwards, however, to 3·1 in Hanley and in Bootle, 3·3 in East Ham, 4·1 in Rotherham, and 4·2 in Barrow-in-Furness. The fatal cases of measles in the 76 towns, which had been 89 and 86 in the two preceding weeks, further declined to 82 in the week under notice, but caused death-rates equal to 1·3 in West Ham and in Preston and 1·5 in Stockport. The 73 deaths from whooping-cough showed an increase of five upon the number in the previous week and caused the highest death-rates, 1·7 in Barrow-in-Furness, 2·0 in Merthyr-Tydfil, 2·3 in Hanley, and 3·3 in Rotherham. The 70 deaths attributed to diarrhœa showed a further slight increase upon recent weekly numbers, and caused the highest death-rates, 1·5 in Bootle and in Blackburn. The 35 fatal cases of diphtheria corresponded with the number in the previous week and caused death-rates equal to 1·0 in Sunderland and 2·2 in East Ham. The 21 deaths from scarlet fever, including seven in London and four in Liverpool, were fewer than in any previous week of this year. The 15 deaths referred to "fever" corresponded with the number in the previous week, and again included three in Norwich, equal to an annual rate of 1·3 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had declined in the eight preceding weeks from 2938 to 2565, had further fallen to 2553 on June 27th; 365 new cases of this disease were, however, admitted to these hospitals during the week under notice, against 289 and 310 in the two preceding weeks. The deaths in London referred to pneumonia and to other diseases of the respiratory organs, which had steadily declined in the nine preceding weeks from 301 to 115, further fell to 107 in the week under notice, and were 44 below the corrected number in the corresponding week of the five years 1903-07. Eight deaths in London were again directly referred to influenza during the week. The causes of 33, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in London, Leeds, West Ham, Bradford, Newcastle-on-Tyne, Hull, and in 52 other smaller towns; eight uncertified causes of death were, however, registered during the week in Liverpool, four in Birmingham, and three of the 19 deaths in Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 13·2 and 14·7 per 1000 in the two preceding weeks, declined again to 14·5 in the week ending June 27th. During the 13 weeks of the past quarter the annual death-rate in these eight towns averaged 16·4 per 1000, and exceeded by no less than 2·6 the mean rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rates during the week under notice ranged from 9·9 and 11·1 in Leith and Aberdeen to 17·8 in Perth and 19·2 in Dundee. The 510 deaths in the eight towns showed a decline of seven from the number in the previous week, and included 40 which were referred to the principal epidemic diseases, against 42 and 51 in the two preceding weeks; of these 40 deaths, 16 resulted from diarrhœa, 12 from whooping-cough, seven from measles, four from "fever," and one from scarlet fever, but not one either from diphtheria or small-pox. These 40 deaths were equal to an annual rate of 1·1 per 1000, the mean rate from the same diseases in the 76 English towns during the same week being 1·0. The 16 deaths attributed to diarrhœa exceeded the number in any recent week, and included six in Glasgow, three in Dundee and in Greenock, and two in Edinburgh. The fatal cases of whooping-cough, which had been 11 and 20 in the two previous weeks, declined again to 12 in the week under notice; four were returned in Aberdeen and three both in Dundee and in Glasgow. The seven deaths from measles were considerably below the numbers in the two preceding weeks, but included four in Glasgow and two in Edinburgh. The fatal cases of "fever," which had been two and five in the two previous weeks, declined again to four in the week under notice; they included two of cerebro-spinal meningitis and one of enteric fever in Glasgow, and a fatal case of cerebro-spinal meningitis in Edinburgh. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 51 and 73 in the two preceding weeks, declined again to 67 in the week under notice, and were seven below the number returned in these towns in the corresponding week of last year. The causes of 13, or 2·5 per cent., of the deaths registered in the eight towns during the week were not stated or not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 19·2 and 16·5 per 1000 in the two preceding weeks, further declined to 16·0 in the week ending June 27th. During the 13 weeks of the past quarter the death-rate in Dublin averaged 20·4 per 1000; the mean rate during the same period did not exceed 13·8 in London and 15·5 in Edinburgh. The 160 deaths of Dublin residents registered in the week under notice showed a further decline of four from the numbers returned in the two preceding weeks, and included 11 which were referred to the principal epidemic diseases, against six and 14 in the two previous weeks. These 11 deaths were equal to an annual rate of 1·5 per 1000, the rate during the week from the same diseases being only 1·0 in London and 0·9 in Edinburgh. Of the 11 deaths from these epidemic diseases in Dublin, four resulted from measles, four from diarrhœa, two from diphtheria, and one from "fever," but not one from whooping-cough, scarlet fever, or small-pox. The fatal cases of measles showed a decline of one, while the deaths attributed to diarrhœa corresponded with the number in the previous week. The 121 deaths from all causes in the city during the week included 25 of infants under one year of age and 42 of persons aged upwards of 60 years; the deaths of elderly persons showed a considerable increase upon the low numbers in recent weeks. Five inquest cases and three deaths from violence were registered, and 61, or 50·4 per cent., of the deaths registered during the week occurred in public institutions. The causes of three, or 2·4 per cent., of the deaths registered during the week were not certified. The causes of all the 991 deaths registered in London during the week were duly certified, while in Edinburgh the proportion of uncertified causes of death was equal to 6·2 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: F. J. Burns to the *Royal Arthur*, additional, for the *Edgar*, temporarily, for manœuvres; B. F. Parish to the *Europa*, additional, for the *Sirius*, temporarily, for manœuvres; and C. G. Matthew to the *Fisgard*. Staff-Surgeons: J. Stoddart, to the *Europa* for the *Æolus*, while on special service at Avonmouth; R. M. Richards to the *Latona*, temporarily, for manœuvres; M. J. Smith to the *Gibraltar*; and E. S. Reid, lent to Deptford Victualling Yard, temporarily. Surgeons: W. N. L. Cherry to the *Gibraltar*; J. G. Peebles to the Royal Marine Infirmary, Chatham; and J. R. A. Clark-Hall to the *Vivid*, additional, for disposal.

ARMY MEDICAL SERVICE.

Lieutenant-Colonel Louis E. Anderson, from the Royal Army Medical Corps, to be Colonel, vice H. Martin, deceased (dated June 5th, 1908).

ROYAL ARMY MEDICAL CORPS.

Captain C. R. Hime has been appointed Adjutant at the Depôt, Aldershot. Captain G. J. Delap, D.S.O., has been appointed a company commander at the Aldershot Depôt, vice Captain C. R. Hime.

Major George Raymond retires on retired pay (dated June 27th, 1908). Captain Lewis J. C. Hearn, from temporary half-pay, is placed on retired pay (dated June 27th, 1908).

Lieutenant Charles M. Drew is seconded for service with the Egyptian Government (dated June 9th, 1908).

INDIAN MEDICAL SERVICE.

The King has approved of the following promotion in the Indian Medical Service:—To be Surgeon-General: Colonel Percy Hugh Benson (dated April 1st, 1908).

His Majesty has also approved of the retirement of the following officers: Lieutenant-Colonel Charles Henry Bennett (dated Feb. 11th, 1908). Lieutenant-Colonel Jarlath ffrench-Mullen (dated May 25th, 1908).

ROYAL ARMY MEDICAL CORPS SCHOOL OF INSTRUCTION.

Captain George G. Delap, D.S.O., R.A.M.C., to be Assistant Instructor, vice Captain H. C. R. Hime (dated June 15th, 1908).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Richard H. Luce to be Surgeon-Major (dated June 17th, 1908).

THE TERRITORIAL FORCE.

Royal Army Medical Corps.

Yorkshire Mounted Brigade Field Ambulance: Captain William Kitson Clayton, from the South Yorkshire Bearer Company, Royal Army Medical Corps (Volunteers), to be Major (dated April 1st, 1908). Captain (Honorary Captain in the Army) George Gardner Oakley, from the West Yorkshire Bearer Company, Royal Army Medical Corps (Volunteers), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Lieutenant Alexander Wetherhead French, from the South Yorkshire Bearer Company, Royal Army Medical Corps (Volunteers), to be Captain (dated April 1st, 1908).

1st Northumbrian Field Ambulance: Surgeon-Captain John Clay, from the 2nd Volunteer Battalion, The Northumberland Fusiliers, to be Major (dated April 1st, 1908). Surgeon-Captain Frederick Newman Grinling, from the 2nd Volunteer Battalion, The Northumberland Fusiliers, to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Lieutenant Frank Hawthorn, from the 1st Newcastle-on-Tyne Royal Garrison Artillery (Volunteers), to be Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). John Maxwell Gover to be Lieutenant (dated April 1st, 1908). James Willie Heslop to be Lieutenant (dated April 25th, 1908). James Percy Milne to be Lieutenant (dated April 25th, 1908). William Simpson to be Lieutenant (dated April 25th, 1908). Frederic George Armstrong to be Lieutenant (dated April 25th, 1908).

2nd Northumbrian Field Ambulance: Surgeon-Captain Laurence James Blandford, from the 1st Volunteer Battalion, The Durham Light Infantry, to be Major (dated April 1st, 1908). The undermentioned officers from the 1st Volunteer Battalion, The Durham Light Infantry, to be Lieutenants, with precedence as in the Volunteer Force: Surgeon-Lieutenant Henry Carden Pearson (dated April 1st, 1908). Surgeon-Lieutenant Duncan Alexander Cameron (dated April 1st, 1908). Surgeon-Lieutenant Douglas Vercoe Haig (dated April 1st, 1908). Surgeon-Lieutenant David Leonard Fisher (dated April 1st, 1908). Surgeon-Lieutenant George Greig Farquhar (dated April 1st, 1908). James Donald Sinclair to be Lieutenant (dated April 1st, 1908).

3rd Northumbrian Field Ambulance: Surgeon-Major Henry George Falkner, from the 1st Volunteer Battalion, The East Yorkshire Regiment, to be Lieutenant-Colonel (dated April 1st, 1908). Surgeon-Captain Arthur Tinsley Sissons, from the 1st Volunteer Battalion, The East Yorkshire Regiment, to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). The undermentioned officers, from the 1st Volunteer Battalion, The East Yorkshire Regiment, to be Lieutenants, with precedence as in the Volunteer Force: Surgeon-Lieutenant Oswald Lucas Appleton (dated April 1st, 1908). Surgeon-Lieutenant Percy Roberts Ash (dated April 1st, 1908).

1st West Riding Field Ambulance: Captain Algernon Edward Luke Wear, from the Northern Command, Leeds Companies, Royal Army Medical Corps (Volunteers), to be Lieutenant-Colonel (dated April 1st, 1908). Lieutenant Alexander Dunstan Sharp, from the Northern Command, Leeds Companies, Royal Army Medical Corps (Volunteers), to be Captain (dated April 1st, 1908). Surgeon-Lieutenant Alexander Brodie Seton Stewart, from the 2nd (Leeds) Yorkshire (West Riding) Royal Engineers (Volunteers), to be Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). James Ewing to be Lieutenant (dated April 1st, 1908).

2nd West Riding Field Ambulance: Captain William McGregor Young, from the Northern Command, Leeds Companies, Royal Army Medical Corps (Volunteers), to be Major (dated April 1st, 1908). The following officers from the Northern Command, Leeds Companies, Royal Army Medical Corps (Volunteers), to be Captains (dated April 1st, 1908): Lieutenant Harold Collinson and Lieutenant Frederick Whalley.

North Midland Mounted Brigade Field Ambulance: Surgeon-Captain Thomas Thompson, from the 1st Volunteer Battalion, The South Staffordshire Regiment, to be Major (dated April 1st, 1908). Arthur Avent to be Lieutenant (dated May 8th, 1908).

1st North Midland Field Ambulance: Captain and Honorary Major Richard Harman Luce, from the Sherwood Foresters Bearer Company, Royal Army Medical Corps (Volunteers), to be Lieutenant-Colonel (dated April 1st, 1908). Captain William James Reid, from the Sherwood Foresters Bearer Company, Royal Army Medical Corps (Volunteers), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Lieutenant Ernest Arnold Wraith, from the Sherwood Foresters Bearer Company, treatment on the bodies of helpless children of a very tender age. Should the unhappy martyr be brought by such ruthless artifice to the brink of death no better remedy is known of than to send speedily for a priest who is expected, for a consideration, of course, to cure the patient by mysterious and meaningless invocations.

Thaumaturgy has a potent influence with the Oriental's disposition; he therefore despises simplicity and gives credit and preference to the mysterious and the complex. Give him a colourless and tasteless medicine and his faith in it, as well as his confidence in the medical man, will at once be shaken. "It is too plain, too artless to be of any use," he will think. But let the prescription be several inches long; let it include a dozen, or even more, of different substances; let these substances be as rare as possible, as bitter or acrid as possible, or even as disgusting as possible, and the Oriental will take them with fullest confidence and think wonders of the physician's skill and learning. He has, in fact, the same notions of the practice of medicine as were held universally by Europeans in the Middle Ages, lingered on amongst the educated classes into the seventeenth and even the eighteenth centuries, and in an attenuated and shamefaced form have not yet entirely died out, as witness the ancient practice of wearing amulets which was revived in this country some few years ago for the relief of rheumatism.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest towns 8820 births and 3664 deaths were registered during the week ending June 27th. The annual rate of mortality in these towns, which had declined in the eight preceding weeks from 15·7 to 11·6 per 1000, rose again to 11·8 in the week under notice. During the 13 weeks of the past quarter the annual death-rate in these towns averaged only 13·8 per 1000, and in London during the same period the rate did not exceed 13·3. The lowest annual death-rates in the 76 towns during the week under notice were 5·2 in Walthamstow, 6·1 in Handsworth and in Newport (Mon.), and 6·6 in Tynemouth; the rates in the other towns ranged upwards, however, to 19·8 in Wigan, 20·6 in St. Helens, 21·6 in Stockton-on-Tees, and 24·5 in Hanley. The death-rate in London during the week did not exceed 10·8. The 3664 deaths in the 76 towns during the week showed an increase of but 42 upon the low number in the previous week, and included but 296 deaths which were referred to the principal epidemic diseases, a lower number than in any previous week of this year; of these 296 deaths, 82 resulted from measles, 73 from whooping-cough, 70 from diarrhœa, 35 from diphtheria, 21 from scarlet fever, and 15 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases last week were equal to a mean annual rate of but 1·0 per 1000, corresponding with the low rate from the same diseases in each of the two preceding weeks; the rate from these diseases in London was again so low as 0·8. No death from any of these epidemic diseases was registered last week in Oldham, Walthamstow, Plymouth, Halifax, and in 12 other smaller towns; the annual death-rate from these diseases ranged upwards, however, to 3·1 in Hanley and in Bootle, 3·3 in East Ham, 4·1 in Rotherham, and 4·2 in Barrow-in-Furness. The fatal cases of measles in the 76 towns, which had been 89 and 86 in the two preceding weeks, further declined to 82 in the week under notice, but caused death-rates equal to 1·3 in West Ham and in Preston and 1·5 in Stockport. The 73 deaths from whooping-cough showed an increase of five upon the number in the previous week and caused the highest death-rates, 1·7 in Barrow-in-Furness, 2·0 in Merthyr-Tydfil, 2·3 in Hanley, and 3·3 in Rotherham. The 70 deaths attributed to diarrhœa showed a further slight increase upon recent weekly numbers, and caused the highest death-rates, 1·5 in Bootle and in Blackburn. The 35 fatal cases of diphtheria corresponded with the number in the previous week and caused death-rates equal to 1·0 in Sunderland and 2·2 in East Ham. The 21 deaths from scarlet fever, including seven in London and four in Liverpool, were fewer than in any previous week of this year. The 15 deaths referred to "fever" corresponded with the number in the previous week, and again included three in Norwich, equal to an annual rate of 1·3 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had declined in the eight preceding weeks from 2938 to 2565, had further fallen to 2553 on June 27th; 365 new cases of this disease were, however, admitted to these hospitals during the week under notice, against 289 and 310 in the two preceding weeks. The deaths in London referred to pneumonia and to other diseases of the respiratory organs, which had steadily declined in the nine preceding weeks from 301 to 115, further fell to 107 in the week under notice, and were 44 below the corrected number in the corresponding week of the five years 1903-07. Eight deaths in London were again directly referred to influenza during the week. The causes of 33, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in London, Leeds, West Ham, Bradford, Newcastle-on-Tyne, Hull, and in 52 other smaller towns; eight uncertified causes of death were, however, registered during the week in Liverpool, four in Birmingham, and three of the 19 deaths in Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 13·2 and 14·7 per 1000 in the two preceding weeks, declined again to 14·5 in the week ending June 27th. During the 13 weeks of the past quarter the annual death-rate in these eight towns averaged 16·4 per 1000, and exceeded by no less than 2·6 the mean rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rates during the week under notice ranged from 9·9 and 11·1 in Leith and Aberdeen to 17·8 in Perth and 19·2 in Dundee. The 510 deaths in the eight towns showed a decline of seven from the number in the previous week, and included 40 which were referred to the principal epidemic diseases, against 42 and 51 in the two preceding weeks; of these 40 deaths, 16 resulted from diarrhœa, 12 from whooping-cough, seven from measles, four from "fever," and one from scarlet fever, but not one either from diphtheria or small-pox. These 40 deaths were equal to an annual rate of 1·1 per 1000, the mean rate from the same diseases in the 76 English towns during the same week being 1·0. The 16 deaths attributed to diarrhœa exceeded the number in any recent week, and included six in Glasgow, three in Dundee and in Greenock, and two in Edinburgh. The fatal cases of whooping-cough, which had been 11 and 20 in the two previous weeks, declined again to 12 in the week under notice; four were returned in Aberdeen and three both in Dundee and in Glasgow. The seven deaths from measles were considerably below the numbers in the two preceding weeks, but included four in Glasgow and two in Edinburgh. The fatal cases of "fever," which had been two and five in the two previous weeks, declined again to four in the week under notice; they included two of cerebro-spinal meningitis and one of enteric fever in Glasgow, and a fatal case of cerebro-spinal meningitis in Edinburgh. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 51 and 73 in the two preceding weeks, declined again to 67 in the week under notice, and were seven below the number returned in these towns in the corresponding week of last year. The causes of 13, or 2·5 per cent., of the deaths registered in the eight towns during the week were not stated or not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 19·2 and 16·5 per 1000 in the two preceding weeks, further declined to 16·0 in the week ending June 27th. During the 13 weeks of the past quarter the death-rate in Dublin averaged 20·4 per 1000; the mean rate during the same period did not exceed 13·8 in London and 15·5 in Edinburgh. The 160 deaths of Dublin residents registered in the week under notice showed a further decline of four from the numbers returned in the two preceding weeks, and included 11 which were referred to the principal show upwards of 40 portraits, many of them of great interest and a few unique. They are grouped under the heads of Xanthelasma and its variations, including the sebaceous and sudoriparous forms; Icteric xanthoma and Glycosuric xanthoma. I must not trespass further on your space than to add that both these exhibitions must be removed in a week or two and that meanwhile anyone wishing to inspect them will be welcome at the Polyclinic, 22, Chenies-street, Gower-street.—I am, Sir, yours faithfully,

JONATHAN HUTCHINSON.

June 29th, 1908.

PRIMITIVE MIDWIFERY IN SOUTH CHINA.

To the Editor of THE LANCET.

SIR,—In the very interesting paper by Professor J. B. Hellier on the Methods of Primitive Midwifery, published in THE LANCET of Feb. 8th, p. 419, the suggestion was made that some readers who have the opportunity of first-hand study of the practices referred to should record their personal experiences. The following observations apply to South China where I am engaged in hospital work. In North and Central China the conditions are different. There, as a rule, women only are allowed to attend to cases of childbirth. Here it is customary for midwifery operations to be undertaken by men as well, and no objection is made to their presence. Naturally, in a Chinese inland town one sees cases which, owing to prolonged labour without assistance, are rarely met with in English practice. One of my first introductions to Chinese midwifery work took place in a village where the woman had been in labour for some five days. The child was a monster with one head, two bodies, four arms, and four legs. The uterus was already ruptured and two of the legs had gone through the rent. Fortunately the resisting powers of the Chinese peasant woman are great. She lives a much more natural life than her Western sisters, and if she has to do more than her share of the rough work in the fields she reaps the benefit when the time comes for the birth of a child.

Professor Hellier divides the development of obstetrics into three stages. China is undoubtedly still in the primitive stage, characterised by an entire absence of knowledge of anatomy and the mechanism of labour. Native doctors, for instance, are taught that in normal labour the child makes its first appearance with the face looking to one side. If it looks downwards it portends the death of the father; if upwards, it portends that of the mother. The treatment resorted to is often cruel in the extreme and as senseless as cruel. It is indeed a wonder that the inhabitants of a country which has been civilised for so many centuries and has shown so much ingenuity and inventive power in the past should have failed to grasp the very elements of midwifery practice.

There is probably no race more fond of all sorts of medicine than the Chinese. Pills, plasters, ointments, concoctions of every variety are always acceptable by the sick Celestial. Consequently one is not surprised at the large number of internal and external remedies for difficult labour. Most of these are given with a view to strengthening the pains. The administration of urine, mentioned by Professor Hellier, is not confined to the Dutch East Indies. In South China it is a well-recognised remedy. But it is always children's urine that is drunk, and almost invariably that of a little boy. Contrary to what one might expect, opium is rarely given. A pheasant ripped open while still alive and placed on the abdomen is supposed to be efficacious, but not so much so as a tiger's intestines. These are worn round the neck with the ends hanging down. Being an expensive remedy, they are usually borrowed for the occasion from some neighbouring medicine shop which keeps them in stock. The midwife is usually an old woman of most uncleanly habits who probably has been summoned from her fields for the occasion and who has had neither time nor inclination to first wash her hands. Even in normal labour she is responsible for a lot of suffering, but it is when delivery is delayed that she does most harm. There are no forceps in Chinese native practice. If the child does not appear after what is judged to be the proper time the midwife inserts her hand and attempts to pull at the first thing she can catch hold of. On one occasion I was called to a case of placenta prævia where the woman had been bleeding badly for some 60 hours. Largely owing to the attentions of the midwives, I found presenting at the vulva the cord, a piece of the placenta, one foot, and two arms. If pulling at the first part which comes to hand prove unsuccessful recourse is had to a knife and the whole vulva is often torn and cut in a most barbarous manner, the urethra not infrequently being irremediably damaged. On two or three occasions I have seen the vulva and the rectum made into one large cavity and the woman almost pulseless from loss of blood. I have felt incisions all round the cervix comparable to the first steps of vaginal hysterectomy. Once I found that somehow or other the native doctor had forced apart the symphysis pubis so that there was a space of an inch between the two pubic bones and a finger could be inserted for two and a half inches into the cavum Retzii.

With such methods of treatment, transverse presentations are naturally very dangerous, and as a matter of fact such cases, not within reach of a foreign-trained doctor, almost invariably die. The treatment pursued is to place a little rice or a few cash into the hand and then to push it back with the idea apparently that having received a present the child will consent to come down in the right way. The next step is to pull on the hand. Sometimes the other arm is brought down, making delivery more difficult still, but I have only seen this once. Usually the further treatment of the case resolves itself into pulling more and more energetically until the woman dies from exhaustion or ruptured uterus. Embryotomy is never done purposely. Sometimes an energetic midwife will open the head in her endeavour to deliver, but this is considered bad practice. As a rule, in cases of impacted head injuries to the child due to the midwife are confined to the scalp, which may be torn right off.

The Chinese have a great horror of a woman dying with the child still unborn. In not a few cases the foreign doctor arrives upon the scene when the woman is just on the point of death. Naturally, in these circumstances, one does not like to interfere, especially if the woman happens to live in a distant village where no foreigner has been before and where consequently there is a crowd of some hundreds of interested onlookers outside the door. The greatest pressure is brought to bear upon the doctor to undertake the case. The oldest man in the family, of most venerable appearance, will come personally to make the request. Once I have had my chair sent away with the intention of keeping me in the house until the child was born. The death of the woman seems unimportant compared to the necessity of delivering the child. A woman who dies in childbirth with the child undelivered is supposed always to remain in hell, and her spirit, never at rest, is believed constantly to harass the family and bring all manner of ill-fortune upon each member. With a view to avoiding this the Chinese sometimes perform Cæsarean section. I have never heard of the operation being attempted when the woman is alive. It is done after death. The operation is performed by one of the local coffin-bearers who form, perhaps, the most degraded class in Chinese society. A nurse informs me that the customary fee is five Mexican dollars, about a month's wages for an ordinary coolie.

A curious superstition among the Chinese women is that sometimes the child is born viâ the rectum. To prevent this some Chinese women refuse to lie down for delivery but sit firmly on their wooden bedboards until the head appears. A few months ago at the house of the local chief magistrate we had for this reason great difficulty in persuading a woman to allow us to attend to her in the ordinary position. I remember this case well as the chief lady of the Yamen was herself an amateur Chinese doctor. She dosed the other women of the establishment with their children, like Mrs. Squeers, and they dare not refuse. I was told privately that she had already killed five or six infants in this way. At the time of the operation it was not etiquette for her or the other wives to be present. I thought I heard some breathing behind my back and looking round found a screen through which several holes had been bored. At each hole there appeared an eye!

As a rule the Chinese midwife does not pull upon the cord in a case of normal labour, and it is to her credit that she will wait for two or three hours for the placenta to be delivered naturally. The woman is given various drugs and

Royal Army Medical Corps (Volunteers), to be Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908).

2nd North Midland Field Ambulance: Captain William Pemberton Peake, from the Leicester and Lincoln Bearer Company, Royal Army Medical Corps (Volunteers), to be Major (dated April 1st, 1908). The following officers, from the Leicester and Lincoln Bearer Company, Royal Army Medical Corps (Volunteers), are appointed to the Field Ambulance with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Captain Montague Shirley Wyatt Gunning and Lieutenant Alastair MacGregor. James Robert Plant to be Lieutenant (dated April 1st, 1908).

3rd North Midland Field Ambulance: Captain Howard Henry Congreve Dent, from the Staffordshire Bearer Company, Royal Army Medical Corps (Volunteers), to be Major (dated April 1st, 1908).

1st South Midland Field Ambulance: Captain Arthur Roscoe Badger, from the Worcester and Warwick Bearer Company, Royal Army Medical Corps (Volunteers), to be Major (dated April 1st, 1908). Surgeon-Captain Cyril Henry Howkins, from the 1st Volunteer Battalion, The Royal Warwickshire Regiment, to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Lieutenant George William Craig, from the Worcester and Warwick Bearer Company, Royal Army Medical Corps (Volunteers), to be Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Lieutenant Seymour Gilbert Barling, from the 1st Volunteer Battalion, The Royal Warwickshire Regiment, to be Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). Cyril Reginald Lunn to be Lieutenant (dated April 1st, 1908). William Malcolm Sturrock to be Lieutenant (dated April 1st, 1908). William McCall to be Lieutenant (dated April 1st, 1908).

2nd South Midland Field Ambulance: Surgeon-Major Charles Thomas Griffiths, from the 1st Volunteer Battalion, The South Staffordshire Regiment, to be Lieutenant-Colonel (dated 1st April, 1908). William Algernon Louis Holland to be Lieutenant (dated April 1st, 1908). John Henry Hobling to be Lieutenant (dated April 1st, 1908). Alfred Alwyne Hingston to be Lieutenant (dated April 1st, 1908).

3rd South Midland Field Ambulance: Surgeon-Lieutenant-Colonel Arthur William Prichard (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Portland Volunteer Infantry Brigade), from the 1st (City of Bristol) Volunteer Battalion, The Gloucestershire Regiment, to be Lieutenant-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Captain James Young, from the 1st (City of Bristol) Volunteer Battalion, The Gloucestershire Regiment, to be Major (dated April 1st, 1908). Bertram Mitford Heron Rogers to be Lieutenant (dated April 1st, 1908). James Smith Mather to be Lieutenant (dated April 1st, 1908). Thomas Arthur Green to be Lieutenant (dated April 1st, 1908). Percy Moxey to be Lieutenant (dated 1st April, 1908).

3rd Home Counties Field Ambulance: Major and Honorary Lieutenant-Colonel John James de Zouche Marshall, from the East Surrey Bearer Company, Royal Army Medical Corps (Volunteers), to be Lieutenant-Colonel (dated April 1st, 1908).

QUEEN ALEXANDRA'S IMPERIAL MILITARY NURSING SERVICE.

With reference to the recent notification that the Army Council had decided to form a reserve of nurses in order to provide for the necessary expansion of *personnel* on the outbreak of war, the Secretary of the War Office announces that regulations for this reserve have now been approved. Among them are the following. A candidate must be between 26 and 45 years of age, single or widow, and possess a certificate of not less than three years' training and service in a civil general hospital or Poor-law infirmary recognised by the Local Government Board as a nurse-training school. Members will be enrolled for a period of three years and must agree to serve at home or abroad as required. An annual retaining fee of £2 will be paid to sisters and staff nurses on the understanding that the grant of this fee to each individual will be reviewed annually. When called upon for duty in military hospitals they will receive the following yearly rates of pay: matron, £75 to £150; sister, £50 to £65; staff nurse, £40 to £45; and the following allowances: (1) allowance in lieu of board and washing—at home 15*s.* a week, abroad 21*s.* a week; or if free messing is provided 3*s.* 6*d.* a week; and (2) clothing allowances—annual clothing and cloak allowance, at home £8, abroad £9; outfit allowances when proceeding on active service, £8 5*s.* On cessation of army employment members whose service has been satisfactory will receive the following gratuities: matron, £15; sister, £10; staff nurse, £7 10*s.* Full particulars and forms of application can be obtained from the Secretary, War Office, Whitehall, London, S.W.

THE BIRTHDAY HONOURS.

The list of birthday honours include the names of Lieutenant-Colonel Johnston Shearer, D.S.O., I.M.S., who has been made a Companion of the Order of the Bath, and of Lieutenant-Colonel Francis F. Perry, I.M.S., Honorary Surgeon to the Viceroy of India, who has been made a Companion of the Order of the Indian Empire.

PRESENTATION TO A VETERAN.

At Llandilo, Carmarthenshire, on June 13th, Brigade-Surgeon Edward Hopkins, A.M.S. (retired), was presented with a life-sized portrait of himself, a tea and coffee service, dinner gong, and a case of silver fish-knives as a mark of respect and esteem by the residents of the district. The portrait shows Mr. Hopkins wearing the old "A.M.D." uniform, with six campaign medals.

Inspector-General of Hospitals and Fleets Robert Grant, R.N. (retired), C.B., has been appointed Deputy Lieutenant for the county of Banff.

"Audi alteram partem."

SPECIAL EXHIBITIONS AT THE CLINICAL MUSEUM.

To the Editor of THE LANCET.

SIR,—We have recently developed a somewhat novel feature in connexion with the Clinical Museum of the Polyclinic Post-Graduate College. Our museum consists almost exclusively of portraits and of models, &c., illustrating the features of disease in the living subject. These have been collected from all available sources and comprise, in addition to original drawings and photographs, a vast number of engravings, plates, &c., taken from atlases and other published works. The collection has accumulated to such an extent that it has become very difficult to know how to display its contents.

Although our Museum, which was built for the purpose, is large it became very inconveniently crowded. We were reluctant to put the drawings away in portfolios where they must of necessity be comparatively hidden. The expedient devised has been to clear the floor of the museum for the purpose of the temporary display of special collections, allowing the great majority to remain in portfolios. In these special collections we exhibit, in classified order, all that the museum possesses in illustration of the topic concerned. After remaining on display for a month or more these collections are removed to make way for others. We have on display at the present time two collections which must shortly be removed and it is on their account that I now ask your kindly aid to make known to those who have not already visited them that they can be seen for yet another fortnight. One of them concerns the eruptions caused by the attacks of blood-sucking insects and other parasites on the skin. This subject is one which has been comparatively neglected in our systematic works and I feel assured that an inspection of the pictorial illustrations which are here arranged, side by side, will much help the practitioner to a more definite knowledge of a really important class of maladies. It includes many of those which have been comprised under such names as *prurigo*, *lichen*, and *urticaria*, and of those to which the adjectives *urticans*, *urticatus*, *pruriginosus*, *hæmorrhagicus*, *infantilis*, *æstivalis*, &c., have been applied.

Our second special exhibition is of representations of the different forms of Xanthoma and its allies, the eruptions which are associated with disorders of the liver and the circulation of bile elements in the blood. In this collection we

NOTES UPON HEALTH RESORTS.

SCANDINAVIAN WINTER HEALTH STATIONS.

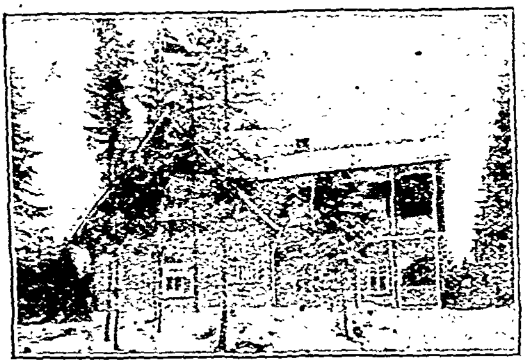
(BY A SPECIAL COMMISSIONER.)

VII.[1]

GOTHENBURG AND DISTRICT.

AFTER Stockholm, Gothenburg is the best centre from which English visitors should explore Sweden. It is easily reached. There are good hotels. Many objects of interest are worthy of a visit, particularly the beautiful Castle Park or Slottskogsparken, the Museum and excellent collection of paintings and sculpture, the Trädgardsföreningen, or gardens of the Horticultural Society, and its extensive general hospital. There is a large and influential colony of English residents in Gothenburg. As a starting point for many interesting excursions by rail or steamer this city presents many advantages. It is also a centre which has been conspicuous in the development of educational and industrial enterprises and has adopted a progressive attitude towards movements aiming at physical and social betterment. The student of medico-sociological problems will find much food for thought in Gothenburg, Sweden's Manchester and Liverpool combined. But it is not with these matters that these articles are concerned. It is desirable that English health and holiday seekers should understand that Gothenburg is the gateway to a district of Sweden which is particularly well suited for health stations, but hitherto almost unknown outside Scandinavia and until recently undeveloped by Swedes themselves. The Göteborg-Boras-Alfvesta railway has opened up Westergotland, a province of Sweden wonderfully rich in natural charms and offering exceptional advantages for the establishment of sanatoriums and health resorts.

FIG. 1.



The Sports Club-house at Hindas.

Through the courtesy of Captain Sprinchorn, the general manager of the line, and under the personal guidance of Mr. Charles Östrand, to whose considerate kindness and wide knowledge I am much indebted, was enabled to explore some of the most attractive parts of this picturesque, admirably engineered, and enterprisingly managed railway. I was particularly struck with the advantages offered by two comparatively new and undeveloped centres on this line, and as at both there is accommodation well suited to the requirements of English visitors I propose to describe the chief features of these hitherto almost unknown resorts. It should be understood that for the unconventional explorer of Nature's retreats and for the holiday-maker who would discover new paths and seek out fresh centres far removed from the haunts of the vulgar tripper and the route of the ordinary tourist the Göteborg-Boras-Alfvesta Järnvägar offers unrivalled opportunities. The line was opened for traffic in 1902 and now provides a way into the heart of Southern Sweden, with its highlands of Smaland, intersected by numerous lakes, and forms a route to Carlskrona, Kalmar, and the south-east of Sweden. The line in several sections of its course rises to a considerable altitude and the surrounding country is peculiarly attractive.[2]

HINDAS.

Twenty-two miles from Gothenburg, and distant only three-quarters of an hour's railway journey, the new health station of Hindas is situated. Although at present quite in its infancy this centre promises to be one of considerable importance in the near future. The very railway station is unusual and at once appeals to the artistic visitor. It is built in the old Swedish style with loggia, and its large hall gaily painted and provided with an open fireplace and quaint chandeliers and brackets for electric lamps give it a peculiarly attractive appearance. Hindas lies in the midst of forests and lakes. The latter are well stocked with fish and afford ample sport for the angler. The place seems to have been first discovered a few years ago by some of Gothenburg's enthusiastic ski-touring sportsmen. Its many advantages as a winter sports centre led to the establishment of a club house by the Gothenburg Sports Union. This is one of the most charming of club quarters (Fig. 1). It is a wooden structure of two storeys. Throughout a naturalness and simple artistic fitness have been maintained, while at the same time requirements for comfort and convenience have not been lost sight of. In one corner of the roomy hall is placed an old-fashioned open brick fire-place where pine logs are burned, scenting the interior with their fragrance. The large club-room is typically Swedish with polished floor and wooden furniture coloured green and red.[3] A library is well supplied with sporting literature. On the ground floor are also kitchen, pantry, and toilet rooms. The bedrooms are situated on the first floor and provision is made

[1] Nos. I., II., III., IV., V., and VI. were published in THE LANCET of April 25th (p. 1233), May 2nd (p. 1306), 16th (p. 1435), and 30th (p. 1578), and June 13th (p. 1717), and 27th (p. 1875), 1908, respectively.

[2] An illustrated handbook to the line has been published: "En Färd Med Göteborg-Boras och Boras-Alfvesta Jährnvägar." Göteborg: Wettergren and Kerber. Price 75 öre. I understand that an English edition is in preparation.

[3] Good illustrations appear in the Club Year-books: "Göteborgs Idrotts Förbunds Arsskrift" Göteborg: Bröderna Töpels Boktryckeri.

foods. Sometimes she is made to vomit and then, as mentioned by Professor Hellier, her own pigtail may be used for the purpose, being thrust down the throat. Should this be of no avail the cord is pulled upon or a special midwife is summoned who, without any previous cleansing, thrusts her hand into the uterus and brings out parts of the placenta. The umbilical cord is left long. It is not cut with a knife or scissors but severed with a broken piece of crockery or bitten through with the teeth. A large number of children die from infection at the umbilicus. The child is usually washed on the third day after birth. When the next bath is given is very indefinite. The baby is fed with rice and cakes on the first day of its existence. I have noticed that the boat women sometimes chew the rice themselves before giving it to the infant. No doubt this assists the child's digestion by supplying some of the starch-converting ferment which is lacking in the infantile economy, but as a rule the rice and cakes are given in the same way as they would be given to an adult. It is not to be wondered at that in these circumstances the mortality among new-born children from digestive complaints is very great.

I am, Sir, yours faithfully,
PHILIP REES, B.A., B.Sc., M.B. Lond.,
Surgeon to the Customs, Wuchow.
Wesleyan Hospital, Wuchow, China, April, 1908.

TRICHOPHYTON AND MICE.

To the Editor of THE LANCET.

SIR,—It may be of interest to your readers if I mention a coincidence that happened to me in connexion with the above subject. Some three years ago I mounted a section of a mouse's testicle and on examining it found it contained a most perfect specimen of pure culture trichophyton. This specimen was put amongst my collection. Some few weeks ago a medical man sent me two tubes of pure ringworm from London to mount four specimens of trichophyton, four of microsporon; in all I mounted about 20. But there was one beautiful specimen and this I compared with the specimen mounted from the mouse; I find the two specimens are exact.

I am, Sir, yours faithfully,
Maldon, Essex, June 29th, 1903. CHARLES DIBBEN.

*** We understand that in the laboratory at St. George's Hospital there has been an epidemic of trichophyton in the mouse. The condition was at first thought to be favus but culture showed it to be a microsporon. It caused some ulceration, indeed the skull seemed to be destroyed by it in places, and possibly some such similar condition might account for the condition observed by Mr. Dibben in the mouse's testicle.—ED. L.

THE STRAWBERRY SEASON.

To the Editor of THE LANCET.

SIR,—The interesting annotation which appeared in THE LANCET of June 20th *in re* "*the strawberry season*," suggested to me in the course of perusal that some of your readers might be glad to know that the semi-popular idea that the strawberry is "good for the gout"—as well as for some other things—is one which has been stamped with the highest botanical authority. The name of the great Swedish physician Linnæus is pretty surely known to most readers of the present generation only as that of the great student of natural history and founder of the modern science of botany, not of the active medical practitioner which he actually was, during the greater part of the period of his most original researches. In his native land of Sweden, as might be expected from a soil and people of strangely romantic history, inspiring scenery, and somewhat uncanny meteorology, the folk-lore medicine of the people, the miracle methods of the clerics, the faith-cure of the quack pretender, and the witchcraft treatment of the wrinkled sorceress, for many centuries included the bulk of the practice of the healing art as carried out in that country. Herbal cures, ranging in value from that of the "All heal"-ing mistletoe downwards, were largely employed by the people of all the Scandinavian territories. One of the medicinal products of the vegetable kingdom which have been largely used by the Swedish people is the wood strawberry, and the belief in the therapeutic efficacy of this fruit has been by no means confined to the peasantry and the unlearned vulgar. Linnæus himself has placed on record the fact that by eating of this fruit he was able to bring a violent attack of gout to a precipitate conclusion, and for the remainder of his life he consumed a maximum quantity of fresh strawberries. There was thus a very good precedent behind the attempted boom of the "strawberry cure of gout" which was made in the latter years of the past century, although the "discoverers" of the "cure" did not, so far as I can remember, quote that authority! And it is of interest to add in this association a passing reference to a still more remarkable specimen of folk-lore prescience of recent—"modern"—discovery in the domain of scientific therapeusis: the Swedish appreciation of the *wintergreen*, which has been time out of mind recognised by the peasantry of that country as a "miraculous" cure for rheumatism, and is on that account popularly known by the highly expressive epithet of *Stat up ach gatt* (Stand up and walk).

I am, Sir, yours faithfully,
Dublin, June 23rd, 1903. JOHN KNOTT.

CHILDREN'S COUNTRY HOLIDAYS FUND.

To the Editor of THE LANCET.

SIR,—The delightful weather of the early summer brings to the minds of your readers happy memories of pleasant holidays spent abroad or at the seaside or in the country and is turning their minds to the days when they will again leave London. May we remind them of the needs of the poor children of London, most of whom have no such happy memories confined as they are to the streets.

The Children's Country Holidays Fund, which is now entering on its twenty-fifth year of work, exists to send the poor children of London into the country for a fortnight's holiday with cottage hosts. All children between the ages of five and 14 attending the elementary schools are eligible without distinction of creed; and in all cases where they can, the parents contribute towards the cost. Last year 41,970 enjoyed a fortnight in the country. May we ask your readers to help us to send 50,000 this year? Every guinea subscribed will provide a fortnight's holiday for two children. All donations, large or small, will be gratefully acknowledged by the Hon. Treasurer, the Earl of Arran, 18, Buckingham-street, Strand, W.C.

We are, Sir, yours obediently,
ALFRED LYTTELTON } Trustees of the Children's
W. F. D. SMITH } Country Holidays Fund.
Buckingham-street, Strand, W.C., June 23rd, 1903.

DIRECT EXCRETORY IRRITATION

To the Editor of THE LANCET.

SIR,—On p. 1776 of your issue of June 20th you have a review of Dr. Norman Walker's new edition of "Introduction to Dermatology." The writer therein remarks: "We agree with the author that most of the substances causing urticaria certainly act as toxins on the skin, probably as they are being excreted, and that they do not cause the disease merely by reflex irritation, as is still often taught," and so on. This passage confirms my theory of the origin of many symptomatic skin rashes by direct excretory irritation. It was first published at the Birmingham meeting of the British Medical Association some 18 years ago. Later, it was somewhat more elaborated in a little volume "Excretory Irritation," published in 1897. The theory has passed through the early stages of derision and neglect and is now virtually adopted by implication in the writings of various dermatologists. Dr. Norman Walker, however, is the only dermatologist who has so far formally and publicly acknowledged my position in the matter—and he has done so in several past editions of his book. To the latter fact I venture to call the attention of your reviewer. Personally I have always been content to accept the position that if my theory attains the established dignity of a general law the question of authorship does not much matter. At the same time I am sure THE LANCET would wish its readers to be accurately informed upon a point of the kind.

I am, Sir, yours faithfully,
Bryanston-street, W., June 29th, 1903. DAVID WALSH.

NOTES UPON HEALTH RESORTS.

SCANDINAVIAN WINTER HEALTH STATIONS.

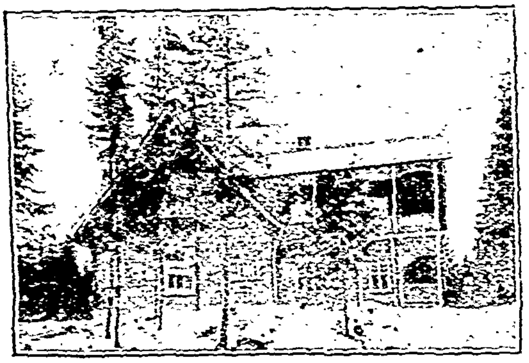
(BY A SPECIAL COMMISSIONER.)

VII.[1]

GOTHENBURG AND DISTRICT.

AFTER Stockholm, Gothenburg is the best centre from which English visitors should explore Sweden. It is easily reached. There are good hotels. Many objects of interest are worthy of a visit, particularly the beautiful Castle Park or Slottskogsparken, the Museum and excellent collection of paintings and sculpture, the Trädgardsföreningen, or gardens of the Horticultural Society, and its extensive general hospital. There is a large and influential colony of English residents in Gothenburg. As a starting point for many interesting excursions by rail or steamer this city presents many advantages. It is also a centre which has been conspicuous in the development of educational and industrial enterprises and has adopted a progressive attitude towards movements aiming at physical and social betterment. The student of medico-sociological problems will find much food for thought in Gothenburg, Sweden's Manchester and Liverpool combined. But it is not with these matters that these articles are concerned. It is desirable that English health and holiday seekers should understand that Gothenburg is the gateway to a district of Sweden which is particularly well suited for health stations, but hitherto almost unknown outside Scandinavia and until recently undeveloped by Swedes themselves. The Göteborg-Boras-Alfvesta railway has opened up Westergotland, a province of Sweden wonderfully rich in natural charms and offering exceptional advantages for the establishment of sanatoriums and health resorts.

FIG. 1.



The Sports Club-house at Hindas.

Through the courtesy of Captain Sprinchorn, the general manager of the line, and under the personal guidance of Mr. Charles Östrand, to whose considerate kindness and wide knowledge I am much indebted, was enabled to explore some of the most attractive parts of this picturesque, admirably engineered, and enterprisingly managed railway. I was particularly struck with the advantages offered by two comparatively new and undeveloped centres on this line, and as at both there is accommodation well suited to the requirements of English visitors I propose to describe the chief features of these hitherto almost unknown resorts. It should be understood that for the unconventional explorer of Nature's retreats and for the holiday-maker who would discover new paths and seek out fresh centres far removed from the haunts of the vulgar tripper and the route of the ordinary tourist the Göteborg-Boras-Alfvesta Järnvägar offers unrivalled opportunities. The line was opened for traffic in 1902 and now provides a way into the heart of Southern Sweden, with its highlands of Smaland, intersected by numerous lakes, and forms a route to Carlskrona, Kalmar, and the south-east of Sweden. The line in several sections of its course rises to a considerable altitude and the surrounding country is peculiarly attractive.[2]

HINDAS.

Twenty-two miles from Gothenburg, and distant only three-quarters of an hour's railway journey, the new health station of Hindas is situated. Although at present quite in its infancy this centre promises to be one of considerable importance in the near future. The very railway station is unusual and at once appeals to the artistic visitor. It is built in the old Swedish style with loggia, and its large hall gaily painted and provided with an open fireplace and quaint chandeliers and brackets for electric lamps give it a peculiarly attractive appearance. Hindas lies in the midst of forests and lakes. The latter are well stocked with fish and afford ample sport for the angler. The place seems to have been first discovered a few years ago by some of Gothenburg's enthusiastic ski-touring sportsmen. Its many advantages as a winter sports centre led to the establishment of a club house by the Gothenburg Sports Union. This is one of the most charming of club quarters (*Fig.* 1). It is a wooden structure of two storeys. Throughout a naturalness and simple artistic fitness have been maintained, while at the same time requirements for comfort and convenience have not been lost sight of. In one corner of the roomy hall is placed an old-fashioned open brick fire-place where pine logs are burned, scenting the interior with their fragrance. The large club-room is typically Swedish with polished floor and wooden furniture coloured green and red.[3] A library is well supplied with sporting literature. On the ground floor are also kitchen, pantry, and toilet rooms. The bedrooms are situated on the first floor and provision is made

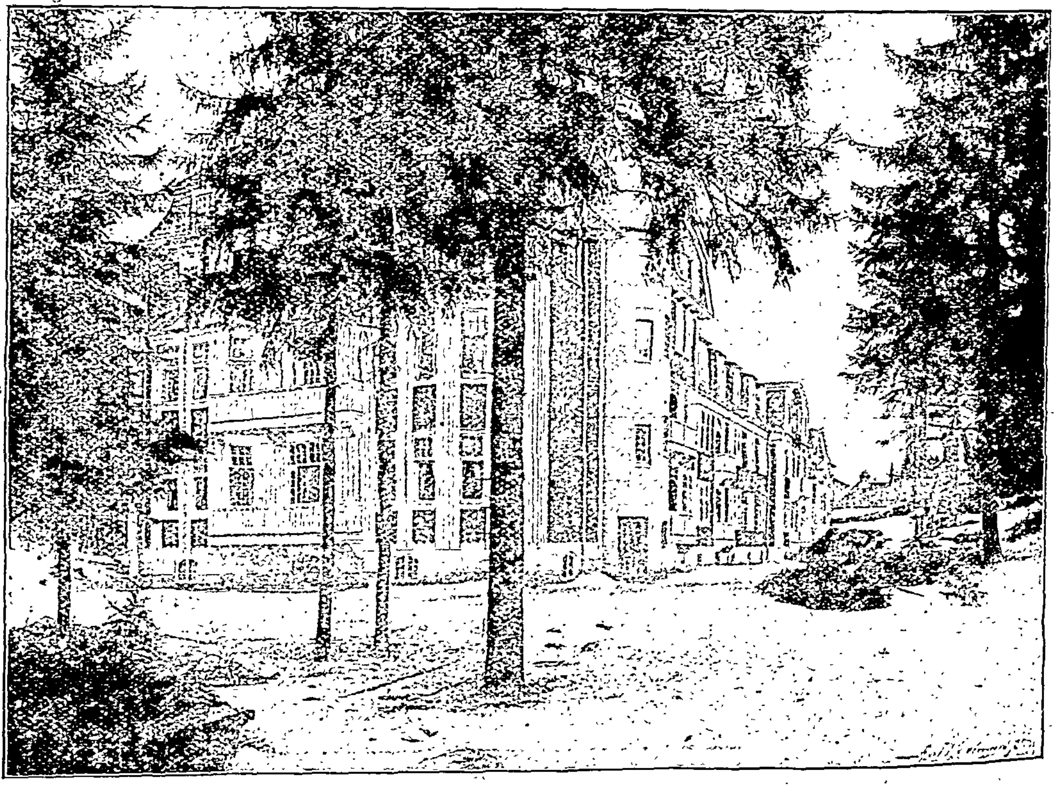
[2] An illustrated handbook to the line has been published: "En Färd Med Göteborg-Boras och Boras-Alfvesta Jährnvägar." Göteborg: Wettergren and Kerber. Price 75 öre. I understand that an English edition is in preparation.

[3] Good illustrations appear in the Club Year-books: "Göteborgs Idrotts Förbunds Arsskrift" Göteborg: Bröderna Töpels Boktryckeri.

for 16 women and 24 men. It must be remembered that in Scandinavia the co-education begun in school days is advantageously continued through youth into adult life, and its benefits are conspicuous in the associations which are natural and necessary for the proper conduct of winter sports. From the balconies delightful views are obtained of Lake Nedsjon, which lies just beneath the club-house. The whole building is warmed by a central heating apparatus and lighted by gasolene. Members of the Union can reside here for a merely nominal fee and have the use of boats, canoes, ice-yachts, skating-sails, skis, and skates on very small payment. The annual subscription is only 16*s.* and I was given to understand that foreign visitors might be admitted to the privileges of membership for short periods. Adjacent is an elaborate and well-constructed ski-jump (Fig. 2). Having climbed to the top I can testify to the glorious outlook there obtained of lakeland and forest and far distant rolling hills. Near by is an excellent toboggan-slide. The lake offers attractions for the skater. Here I experienced the exhilaration and fascination of ice-yachting, and if for no other reason than enjoying this delightful form of winter sport a visit to Hindas is strongly to be recommended.

FIG. 3.



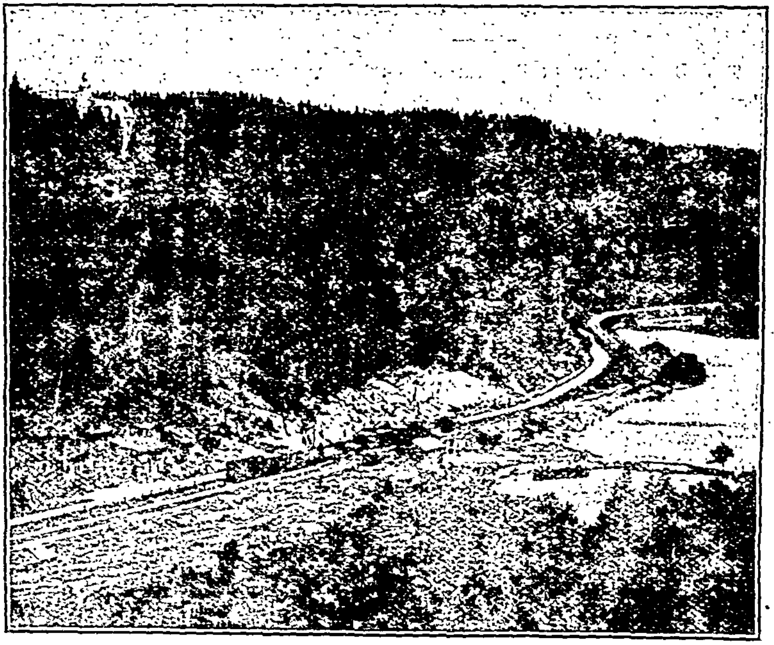
The new Tourist Hotel at Hindas.

The Hindas Tourist Hotel is one of the most artistic, comfortable, and ably conducted establishments of its kind in Sweden (Fig. 3). Having spent a night here and thoroughly inspected all parts of the building and grounds I am in a position to form an opinion. In architectural features the building is characteristic of the best modern Swedish style. It is constructed of wood. Its exterior in red and white makes an effective impression and forms a pleasing contrast to the setting of dark pines which closely surround it. The central hall forms a specially attractive lounge and meeting-place. It is wainscoted in dark green and provided with light green panels, the high ceiling being supported on heavy wooden beams of the same colour. A double staircase leads to a balcony running the whole length of the hall supported by pillars of green-stained wood picked out here and there with bright red. The colouring adopted in Sweden, and indeed throughout Scandinavia, seems to exercise a peculiar psychological influence which is at once soothing and stimulating. A large open fireplace, provided for the burning of pine logs, adds an old-fashioned and homely appearance which English sportsmen will know how to appreciate. The dining-room and other apartments are excellent. There are 63 bedrooms. Each has its own little lobby and most are provided with a balcony. The sanitary arrangements leave nothing to be desired. A water-closet system is provided throughout. There are also first-class baths. The most surprising thing about the place is the comparatively low charges, as they seem to an Englishman, for inclusive board and lodging can be had from 6*s.* a day. No doubt at every season of the year Hindas can offer attractions to the visitor seeking rest and health, but its chief charms to those who have seen it in winter would seem to be most evident, at least to the sportsman, when the lake is ice-gripped and the snow-covered forests and hills call for the devotees of the ski. If apology is needed for dwelling enthusiastically and at length on the delights of Hindas I can only offer the excuse that I would share my experiences with other Britishers.

HULTAFORS.

A few miles beyond Hindas the country assumes a somewhat wilder aspect. At Hultafors on the mountain slopes overlooking the Viared lake a new hydropathic establishment and climatic cure station has recently been opened. Dr. Klas Björkman, the visiting physician, very kindly showed me over the whole building. Hultafors is at present little more than a station and a sanatorium, as will be seen from the accompanying illustration (Fig. 4). A new station is being built and as Gothenburg is only 36 miles distant and the service of trains very good the place should develop rapidly. The hydropathic establishment is admirably placed on the hillside, surrounded by forests of pine, birch, mountain ash, oak, alder, and hazel, and allowing of extensive views over the lake below and distant mountains and forest lands. The altitude is said to be about 850 feet above sea level. The building is thoroughly up-to-date both in its planning and its equipment. It is angled and faces south and thus forms a veritable sun-trap and thorough shelter from the most trying winds (Fig. 5). In the lowest storey are placed the baths which are very complete and allow of the administration of almost every kind of hydrotherapeutic measure and the chief forms of electrical treatment. The lounge-hall, dining, and other public rooms have been well designed. The bedrooms, of which there are 60, and the private apartments are excellent, nearly all looking out southwards over lake and forest, and in many instances being provided with balconies. Heating is maintained by a central hot-water system. Electric light is provided throughout. The sanitary arrangements are good, a complete water-closet system having been installed.

FIG. 4.

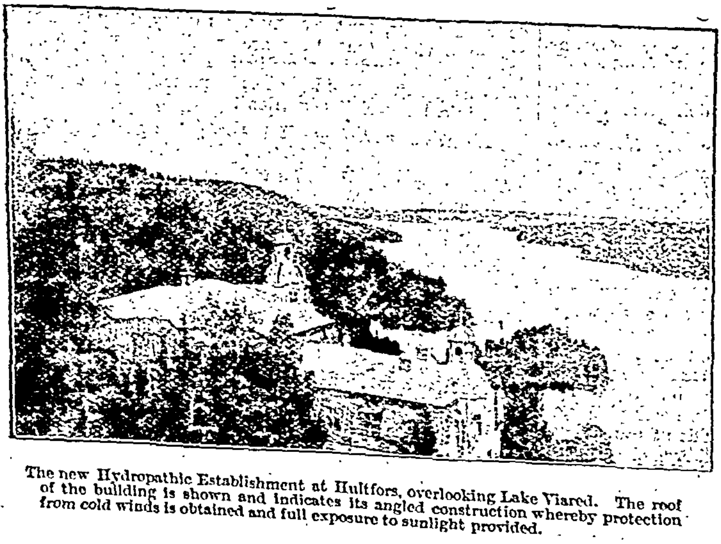


Hultafors, showing the line of the Göteborg-Boras-Alfvesta Railway, with the edge of Lake Viared on the right and the new Hydropathic Establishment amidst the trees on the hillside to the left.

Hultafors is an ideal resort for the weary worker seeking rest for mind and body. Here the convalescent may recuperate, the overwrought obtain relief from the stress and strain of bustling life, and the neurotic, the delicate, and the invalid obtain hygienic oversight, nursing and medical supervision, under the best possible climatic conditions and with ease and comfort almost amounting to luxury. At the time of my visit a well-trained nurse, experienced in Swedish massage and medical gymnastics, was in residence. Tuberculous cases are not admitted. Special attention is devoted to patients requiring regulation of diet.

Although primarily intended for cases requiring more or less medical direction and care, visitors desiring renewal of health and mental vigour by a participation in the milder forms of winter sport will be welcomed. The inclusive tariff ranges from kr. 5.50 (5*s*. 6*d*.) a day, with a charge of 1 kr. a day for a complete hydropathic course. Medicated, electric light, and massage baths are charged at from 25 to 75 öre a bath. These terms appear to be remarkably reasonable. There are many English patients and health and holiday seekers for whom the simple hygienic life is essential who are debarred by the prohibitive prices of *many of our* fashionable homeland establishments. For such, as well as for those who would practise something of Swedish winter sports for themselves, Hindas and Hultafors are thoroughly to be recommended.

FIG. 5.



The new Hydropathic Establishment at Hultfors, overlooking Lake Viared. The roof of the building is shown and indicates its angled construction whereby protection from cold winds is obtained and full exposure to sunlight provided.

THE ROYAL INFIRMARY, LIVERPOOL, AND THE LATE MR. A. F. WARR.—A meeting of the citizens of Liverpool was held at the Town Hall on June 16th, under the presidency of the Lord Mayor (Dr. Richard Caton), to promote a memorial to the late Mr. Augustus Frederick Warr, formerly M.P. for one of the Liverpool divisions and a prominent member of the committee of the Royal Infirmary, in recognition of his personal worth and eminent public services. Mr. Ralph Brocklebank (the chairman and treasurer of the Royal Infirmary), in supporting the motion, said that Mr. Warr was closely associated with him in the management of the Royal Infirmary. It was to Mr. Warr that they owed the charter of the infirmary and he helped the committee in every possible way. There were two institutions in which Mr. Warr was always deeply interested—the University and the Royal Infirmary—and without appearing to be antagonistic to the propositions of the previous speakers he would very much like to see Mr. Warr's name, if the funds would render it possible, associated in some way with the hospital for which he had done so much. Nothing, he thought, could be better than the endowment of a bed at the infirmary, with a tablet suitably inscribed, but he merely offered this as a suggestion.

ELEVENTH FRENCH MEDICAL CONGRESS AT GENEVA.—This congress, as already announced, will take place at Geneva from Sept. 3rd to 5th. Medical men intending to take part in the congress can obtain from the office of the Paris, Lyons, and Mediterranean Railway at 188, Rue St. Lazare, Paris, railway tickets from Paris to Geneva at a discount of 50 per cent.

for 16 women and 24 men. It must be remembered that in Scandinavia the co-education begun in school days is advantageously continued through youth into adult life, and its benefits are conspicuous in the associations which are natural and necessary for the proper conduct of winter sports. From the balconies delightful views are obtained of Lake Nedsjon, which lies just beneath the club-house. The whole building is warmed by a central heating apparatus and lighted by gasolene. Members of the Union can reside here for a merely nominal fee and have the use of boats, canoes, ice-yachts, skating-sails, skis, and skates on very small payment. The annual subscription is only 16*s.* and I was given to understand that foreign visitors might be admitted to the privileges of membership for short periods. Adjacent is an elaborate and well-constructed ski-jump (Fig. 2). Having climbed to the top I can testify to the glorious outlook there obtained of lakeland and forest and far distant rolling hills. Near by is an excellent toboggan-slide. The lake offers attractions for the skater. Here I experienced the exhilaration and fascination of ice-yachting, and if for no other reason than enjoying this delightful form of winter sport a visit to Hindas is strongly to be recommended.

The Hindas Tourist Hotel is one of the most artistic, comfortable, and ably conducted establishments of its kind in Sweden (Fig. 3). Having spent a night here and thoroughly inspected all parts of the building and grounds I am in a position to form an opinion. In architectural features the building is characteristic of the best modern Swedish style. It is constructed of wood. Its exterior in red and white makes an effective impression and forms a pleasing contrast to the setting of dark pines which closely surround it. The central hall forms a specially attractive lounge and meeting-place. It is wainscoted in dark green and provided with light green panels, the high ceiling being supported on heavy wooden beams of the same colour. HULTAFORS.

A few miles beyond Hindas the country assumes a somewhat wilder aspect. At Hultafors on the mountain slopes overlooking the Viared lake a new hydropathic establishment and climatic cure station has recently been opened. Dr. Klas Björkman, the visiting physician, very kindly showed me over the whole building. Hultafors is at present little more than a station and a sanatorium, as will be seen from the accompanying illustration (Fig. 4). A new station is being built and as Gothenburg is only 36 miles distant and the service of trains very good the place should develop rapidly. The hydropathic establishment is admirably placed on the hillside, surrounded by forests of pine, birch, mountain ash, oak, alder, and hazel, and allowing of extensive views over the lake below and distant mountains and forest lands. The altitude is said to be about 850 feet above sea level. The building is thoroughly up-to-date both in its planning and its equipment. It is days old. He illustrated his observations by a model and with the aid of lantern slides and sections. New light was thrown upon the development of the choroid plexuses in the lateral recesses of the fourth ventricle and upon the growth of the pituitary body by a model of a young developing brain, which was demonstrated by Professor P. Thompson, and the earlier stages of the growth of the lower jaw were beautifully illustrated by a series of excellent reconstruction models prepared and exhibited by Professor E. Fawcett. Professor A. M. Paterson showed a series of preparations in support of his contention that the so-called ampulla of the rectum is not a reservoir in which fæces are retained for a certain period before expulsion but a practically closed canal. He admitted that in cases of chronic constipation the ampulla might be filled and distended with fæcal matter, but he urged that such a condition was not normal. In the discussion which followed his demonstration many differences of opinion were developed and the subject is evidently one which requires further investigation. Mr. C. A. Leedham-Green summarised the opinions and evidence regarding the sphincter of the bladder and proved conclusively that the sphincter apparatus at the upper end of the prostatic urethra is an important and effectual mechanism. Professor G. Elliot Smith gave a most lucid explanation of the methods of mapping out the areas of the brain cortex and presented a new chart of the areas modified from those which have previously been published in accordance with the results of his more recent work. He also drew attention to the frequent presence of the infantile type of urinary bladder in adult negroes and Egyptians and pointed out the necessity of remembering its occurrence in the performance of operations in the lower part of the abdomen. Professor D. E. Derry of Cairo explained the methods to be adopted in recognising the sex of innominate bones. He laid great stress upon the presence of a preauricular sulcus as indicative of the female bone. Professor Alexander Macalister confirmed Professor Derry's observations. Mr. Wood Jones exhibited a number of peculiar bones and fragments of bone discovered in excavations in Nubia in the hope of extracting information regarding their peculiarities from the members of the society; he received, however, little help, for the peculiarities were of a particularly uncommon nature. In the afternoon the members of the society were entertained at a most delightful garden party given by the Dean of the Medical Faculty of the University and Mrs. Barling. The proceedings terminated with the usual annual dinner to which Mr. C. B. Lockwood, the first secretary of the society, had been invited as the chief guest to celebrate the society's attainment of its majority, the present year being the twenty-first of its existence.

Hospital Saturday.

June 20th was Hospital Saturday in Birmingham and if the amount paid into the bank on that and the closely following days may be taken as a criterion it appears probable that a new record may be made. Last year the £20,000 which the late Sir William Cook had worked and hoped for was attained and he had the pleasure caused by the realisation of his wishes, but it seems for the moment, at all events, that last year's collection will be exceeded this year. On June 20th the amount paid into the account of the fund was £14,733, or £127 more than last year, and by June 25th the total sum had increased to £17,745, a sum which exceeded that paid in the same period last year by £393. It is also worthy of note that the number of contributors was somewhat smaller than last year. If the indications are correct and the final total is still larger than it was last year, it is to be hoped that the controllers of the fund will see their way to increase the amount which they devote to the hospitals, for the amount of work which the hospitals do for the community, from whom the Hospital Saturday Funds are derived, has increased very greatly and it may be suggested without any unfairness that the sum subscribed to the hospitals from the fund has not increased in relative proportions.

The Feeble-minded.

The statement made by Mrs. Pinsent at a recent meeting of the Birmingham Education Committee will make all thoughtful and far-seeing people still more anxious than they have been that wise and firm laws shall be made as soon as possible to deal with the feeble-minded and to enable them to be placed under proper care and control. Mrs. Pinsent is not usually pessimistic, but she seemed to be depressed by the fact that the result of work of the special schools in this district was that only 19 per cent. of the individuals who had passed through them became wage-earners and only 3 per cent. were earning 10*s.* a week. The conclusion which she drew from the evidence at her disposal was that the majority of defectives require care and protection during their whole lives. If she had gone further and said all, rather than the majority, and had she suggested that restraint in addition to care and protection was required, she would probably have put forth more completely the opinions of most of those who have devoted any careful thought to the problem.

June 30th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Deaths under Anæsthetics.

AN inquest was held recently at the Manchester coroner's court on a tinsmith, aged 42 years, who had lived in Hulme. He underwent an operation on the Wednesday, having been admitted to the Withington Poor-law hospital on the previous Saturday. Chloroform was given and the man very soon collapsed. Artificial respiration was tried but without success. The medical evidence was that death followed the action of chloroform on a weak heart. The deputy coroner (Mr. Sellers) said: "The man was suffering from such a form of heart disease as would make him liable to die under an anæsthetic." One need not perhaps infer that this was intended as a rebuke to the medical men engaged in the case, but it may at all events bear the interpretation that this was a case where if an anæsthetic were administered at all it should be done with extreme caution. There was no evidence given to show that all possible precautions were not carried out and the jury returned a verdict of death from chloroform "which had been skilfully administered." The public mind, however, is a little anxious about deaths under anæsthetics and the jury added "that they thought it desirable a visiting surgeon should be present, if possible, when an anæsthetic was administered." The deputy coroner said he agreed with that expression of opinion. Nor is the medical profession in general likely to dissent from it, for, putting away any feelings of humanity which, though often forgotten, are common to us, as to the rest of mankind, the safety of the patient is instinctively, and not as a mere matter of self-interest, the first aim of the profession. Still, if the attitude of a certain London coroner is to become general, the medical profession will, from the mere feeling of self-preservation, find it necessary to be even more cautious than ever as to the cases to be operated on, either with or without anæsthetics.

Poisoning and Stupidity.

About a fortnight ago a widow, aged 57 years, poisoned herself with carbolic acid. She was sober when she bought the acid, which was wanted, she said, for disinfecting purposes, but drunk when she went to the house of her daughter-in-law, to whom she said she "was going to do it," adding, "Put some flowers on my grave." She had the poison in her pocket, went home, drank a quantity of it, and died in due course. She had often fretted over the death of a daughter a few years ago and said that she did not care how soon she was with her. The stupidity or callousness of the relatives excited the surprise of the deputy coroner who said it was extraordinary that though she told a daughter-in-law "she was going to do it" no one took the bottle from her or watched her after she left the house. The verdict, of course, was the usual one of "Suicide while temporarily insane," but the jury thought that the coroner should censure the relatives for "their stupid behaviour." This Mr. Sellers did, adding that he thought they had been somewhat callous. A relative said, "No, we were not callous; we never thought mother would do it." Giving the relatives—they can scarcely be called the friends—of this woman the benefit of the doubt as to being callous it is difficult to understand the crass

THE FRANCO-BRITISH EXHIBITION.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE DIFFICULTY IN REGARD TO THE LAVATORIES.

THOUGH there are still cases that have not been unpacked and others that have not yet even arrived, nevertheless, for all practical purposes, it may now be said that the Franco-British Exhibition is ready and well worth visiting. Exhibitions are never really ready at the day of opening but this particular exhibition may boast of having broken the record in respect to unpreparedness. The worst phase of this delay led to some widely published complaints. There is no doubt that on the opening day there were regrettable scenes round and about the lavatories. For this circumstances which no one could control, such as the bad weather, were to blame as well as the lack of foresight on the part of individuals. Who these individuals were, however, it would be difficult to say, for one and all, with a unanimity worthy of a better cause, blame each other and fail to recognise that they were themselves in any way at fault. There is the exhibition management on one side and various concessionaires on the other, and it would require a wise judge to say which of all these was the most negligent. But, as already observed, there were also special circumstances that greatly aggravated the trouble.

In the long passage-like succession of halls and sections, the Sections 1 to 8 that stretch from Uxbridge-road to the Wood-lane entrance of the main building, there are four lavatories. On the opening day vast crowds came that way but hurried forward and never noticed these lavatories or thought to retrace their steps so as to come back to them later in the afternoon. The public crowded to the Court of Honour. After the opening ceremony there was a great congestion of people between the Court of Honour, the Élite Gardens, and the Stadium. Inside the Stadium there are eight lavatories and two urinals. But the people did not think of going inside to look for them. Now the four lavatories that are on the same side of the Stadium as the Élite Gardens have had openings and doors made so that they can be reached from outside as well as from inside the Stadium. Had this been done before the opening day these lavatories would have rendered a great service. Also but for the rain and the terrible amount of mud the crowds would have scattered and have wandered towards the semicircle which contains the colonial exhibits. Here there are two lavatories by the horticultural section, and eastwards two more by the New Zealand pavilion. Further east at the end of the French Palace of Applied Arts there are also to be found a ladies' lavatory and a gentlemen's lavatory. In the centre where the great crowd congregated there were two lavatories, one on each side of the grand restaurant, which could have been used although the building was not quite finished. Undoubtedly the accommodation was insufficient, but there would have been much less cause of complaint if the public had only known where to go. While the lavatory known as No. 9 was invaded by a crowd of distressed ladies and scenes were witnessed which were certainly unseemly there were other lavatories not so very far away which were almost deserted.

Turning from the past to the present there are actually 28 lavatories in working order in the grounds, that is 14 for ladies and 14 for gentlemen; others are in course of construction. There will be four more available in a few days. Then there are also a number of private lavatories as well, notably those connected with the restaurants. The question now arises whether this will be sufficient. The difficulty is to prevent congestion. The people should go away from the crowd instead of seeking a lavatory close to where they see the largest accumulation of visitors.

Last week, when the exhibition was crowded because it was splendid cloudless weather and an early closing day, a lady undertook to visit the lavatories on behalf of THE LANCET. With but one exception there was plenty of room everywhere and no need to wait. But at the ladies' lavatory near the Senegalese village every closet was occupied and eight or ten persons were standing waiting either inside or outside the small structure. Among them there was a woman with two children who had no small change. The attendant told her there was time to go to buy something so as to get change before it would be her turn. This certainly seemed a double hardship, particularly as there were children to complicate the difficulty. Surely the attendants should be able to change at least small coins. Just opposite this particular lavatory there are the toboggan Liloise and the giant flip-flap, and these, with other minor side shows, draw many people to this part of the grounds. It is true there are other lavatories that are not far away, at the Grand Restaurant and under the Stadium, in a line with the Grand Restaurant. But the overcrowded lavatory is the first to catch the eye of the visitors as they emerge from the semicircle of the colonial exhibits. There being thus both optical and topographical reasons calculated to produce the overcrowding of one or two particular places, if these lavatories cannot be enlarged in size or more built on the same spot, a conspicuous notice might be posted indicating the way to the other nearest lavatories. Indeed, if these had been all marked down on the Exhibition map a great deal of suffering might have been avoided and many unpleasant incidents would never have occurred. England has, with just pride, considered itself the first nation in the world to construct and to introduce sanitary closets and to establish in this respect the highest standard of decency and cleanliness. Yet at this exhibition, where as a nation we should have put our best foot forward, especially in regard to sanitation, we seem on this occasion to have failed utterly to maintain our reputation. Far be it from me to attempt to pronounce an opinion or to blame individuals. But for a great exhibition to prove truly successful, above all commercial and private interests there must be a supreme influence which represents the nation as a whole. Otherwise it will degenerate into a money-making show. The energy and enterprise of individuals instead of being directed to securing a common and national success will be wasted in unseemly and unprofitable strife against each other. We shall have concessionaires showing their teeth at the general management and the general management excusing itself on the ground of the concessionaires' incapacity, while the public will suffer and the national honour is compromised.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE summer term is rapidly drawing to a close and the examinations in the various faculties are either proceeding or are over. The total number of candidates presenting themselves for examination is 569, or 80 more than last year. This increase in number may perhaps be taken as a criterion of the steady advance which the University is making and of the increasing hold which it is gaining upon the inhabitants of the city and the surrounding districts. The greatest increase in numbers has been in the Faculty of Science. This cannot be wondered at, for the advantages enjoyed by its members are so obvious that they are readily grasped at. The advantages offered by the Medical Faculty are, however, quite as great, even in the early parts of the course, and the clinical material is excellent.

The Summer Meeting of the Anatomical Society of Great Britain and Ireland.

The summer meeting of the Anatomical Society was held in the anatomical department of the University on June 26th, and, judging from the expressions of opinion of those present, it proved to be one of the most successful summer meetings not only on account of the numbers present but also because of the importance and interest of the subjects discussed. One of the striking features of the meeting was the exhibition and description of a number of reconstruction models illustrating various developmental phenomena. Professor Arthur Thomson, the President of the society, showed a model of a developing human eye. This model not only made very clear the relationships of the various parts, but it suggested that perforations were present in the outer layer of the retina at an early stage of development through which mesoblastic cells might pass and form the foci of sarcomata which are known to originate in that region. Dr. A. Bryce described the main features of the youngest human embryo known which he estimated to be about 13

Tydvil are now well supplied with water, but other populous districts such as Pontypridd and the Rhondda valleys and some parts of the Aberdare valley are not so well circumstanced and the conditions of these mining localities are such that supplies must be sought outside the coal field where subsidences are not likely to occur. There is little doubt therefore that the county council will have to persist in its efforts to obtain a general supply.

Municipal Lodging-house for Swansea.

Although there has been for some years in Swansea at least one excellently managed large private common lodging-house the report of a committee of the corporation makes it clear that there is also room for a house managed by the corporation. At a recent visit of the committee to one house all the beds were found occupied and in addition 25 persons were found in the kitchen, and in another house no fewer than 45 persons were crowded together in the kitchen.

Newport Corporation Sanatorium.

The experiment made by the Newport corporation in treating six consumptive patients in a wooden pavilion in the grounds of the Isolation Hospital has been sufficiently successful to warrant the sanitary committee in recommending that six more beds shall be utilised at an additional cost of £300 per annum.

Death of Mr. Henry Cecil Moore.

The medical profession in Hereford has sustained a severe loss through the death on June 21st of Mr. H. Cecil Moore, the medical officer of health of the city, at the age of 72 years. Mr. Moore was the son of Brigadier-General Moore and was born in Lucknow. While still in his teens he joined the Royal Engineers and was attached to the forces engaged in the suppression of the Indian Mutiny. Subsequently he was connected with the Public Works Department and for two years was commanding Engineer and Governor of Perim Island. After service in Ireland ill-health necessitated his retirement from the army on half-pay in 1866. A few years later he decided to study medicine at the Queen's Hospital, Birmingham, and in 1872, having graduated as M.R.C.S. Eng., L.S.A., he was elected house surgeon to the Hereford Infirmary, a post which he held for seven years, when he started in private practice in the town. For a short time he was deputy medical officer of health of the Herefordshire combined sanitary district and for the past eight years had been medical officer of health of the city of Hereford. He took up the study of public health questions with remarkable keenness and was a careful student of current public health literature, with the result that he has left behind a most valuable series of annual reports. There is no doubt that if Mr. Moore had entered the public health service at the beginning of his medical career he would have risen to a very high position in the service, for his training as an engineer, his eminence as a geologist, and the skill with which he collated facts relating to his inquiries would have proved of the greatest assistance to him. For more than 20 years he was secretary of the Woolhope Field Naturalists' Club and during nearly the whole of that period edited the transactions of the club. Quite recently he was elected the President for the second time. The success of this club is in a great measure due to the energetic service which he gave to it. Mr. Moore is survived by his widow.

June 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Victoria Hospital for Consumption, Edinburgh.

THE eighteenth annual report of this charity contains many interesting details of the work of the Victoria Dispensary, which has become an acknowledged model for the conduct of anti-tuberculosis operations. That part of the work which is done at the patients' own homes is of great value to the community, for not only is each one visited and given full instructions by a medical officer after study of his particular hygienic environment, but, whenever possible, other members of his family are submitted to examination. In this way a number of unsuspected cases have been discovered. Thus a single case brought 15 patients under the direction of the dispensary at an obviously more hopeful state of their disease than otherwise would have been the case. So wide are the operations of the dispensary that it notified 50 per cent. of all the cases in Edinburgh revealed by the first year's adoption of compulsory notification in that city. Its records show that in certain tenements every floor and almost every dwelling have their case of tuberculosis, and that patients who change their lodgings often assist in spreading the disease. The results have been most satisfactory with regard to patients treated early, and the recent addition of two new pavilions, which with a new dining-hall and administration block were opened by Mr. A. J. Balfour in October last, has considerably reduced the time which they must spend on the waiting list. The hospital has adopted a definitely graded system of work for suitable patients and is now desirous of founding a working colony which will raise supplies for the hospital by the labour of convalescent patients, as it is felt that such a provision for hardening them off before they return to their usual avocations will add considerably to the value of their treatment. A sum of £5000 would suffice to start the scheme.

Prevention of Cruelty to Children.

The annual meeting of the Glasgow branch of the Scottish National Society for the Prevention of Cruelty to Children was held last week. The annual report stated that the total number of cases reported and investigated had been 1870, an increase of 265 over the previous year. These cases involved 2187 parents or guardians, of whom 1998 were dealt with by warning and advice, and when other means failed by prosecution. Of the latter 153 were imprisoned or fined, and 36 were convicted and admonished by the court. The number of children involved was 5583, an increase of 904 over the previous year. The ordinary income amounted to £1386 and the legacies to £1009. The expenses for the year amounted to £1495.

Objection to the Word "Asylum."

At a meeting of the Glasgow District Lunacy Board last week a motion was brought forward that, except as required by statute, the asylums in the district should be called the "Glasgow District Mental Hospitals." It was pointed out that there was no objection to the word asylum *per se*, but it had come to mean in the minds of the public a place of detention, whereas the institutions were really places of healing. The motion was defeated.

Sanitary Inspectors' Association of Scotland.

The annual congress of the Sanitary Inspectors' Association has just been held at Dunfermline, about 50 members taking part. A civic welcome was extended to the visitors by the provost and thereafter various subjects were discussed, including Methods of House Construction, the Sanitary Aspects of the Housing Problem, and the Method of Dealing with Refuse by Fire.

Aberdeen Accident Inquiry Court: Attack on the Royal Infirmary.

At the Accident Inquiry Court held at Aberdeen on June 18th an inquiry was held in regard to the death of Hugh McLauchlan, aged 16 years, a labourer, residing at 414, George-street, Aberdeen. McLauchlan was employed at a local granite works and on May 11th he missed his footing and stepped into a tank of boiling water and was scalded severely. He was taken to the Royal Infirmary, where he developed measles. He was then removed to the City Hospital for Infectious Diseases and died there on May 16th, the day of admission. Dr. A. G. Anderson, the resident medical officer at the City Hospital, questioned as to the condition of the boy on admission, stated that he was in a state of slight collapse but that there was no reason to think when he was admitted that the boy would die so soon. Mr. Aitken, who appeared for the relatives, addressed the jury and said that it seemed to him that there was room for the jury having something to say as to the removal of the boy. He thought it was for the jury to give their opinion as to whether it was a proper thing to remove this boy who was undoubtedly in a very low state—in a state of collapse—from the centre of the town to the City Hospital. He thought it was a most improper thing to do. The Fiscal said that the infirmary people did not get any notice of the attack that had been made upon them and held that such notice should have been given. The jury in their verdict said that they were of opinion that the medical officers of the infirmary should have been represented at the inquiry to give a reason why the boy was removed in such a precarious condition.

stupidity which allowed this woman to go away and to poison herself without let or hindrance. It is difficult to understand such a condition of mind. Is it the fault of our system of education, compulsory for a period which would include the lives of most of the poor creature's younger relatives, or is it that the "feeble-minded" form a larger proportion of our population than we realise?

"*County Medicos.*"

The above somewhat disrespectful title heralds the notice of the annual dinner of the Lancashire and Cheshire branch of the British Medical Association in one of the Manchester papers. It was held on June 17th at the Queen's Hotel under the presidency of Dr. C. J. Renshaw, and was well attended. Sir William J. Sinclair proposed the toast of the evening, "The British Medical Association," in a speech which contained much wise counsel. He suggested that after such events as the elections to the council the decision of the majority should be accepted so far that the minority should decide to give the successful side a fair chance. He saw no reason why they should quarrel, "except in a genial sort of way." He thought that more attention should be paid to legislation involving the interests of the profession and instanced the Notification of Births Act as being perhaps an outcome of their negligence and added, "the sooner it was repealed the better would it be for the profession at large." Similarly, with the Midwives Act, the sooner it was amended the better. The toast of "The Guests" was proposed by Sir James Barr and responded to by Bishop Welldon, Dean of Manchester, who spoke of the close association of the Church with the medical profession, and thought that "as the inter-relation of the various parts of man's nature came to be better understood the medical and clerical professions would find themselves in closer union than ever. There were mysteries which remained for the present unsolved and the solution of those belonged partly to theirs and partly to his own profession." The health of "The President" was received with musical honours.

June 30th.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

The Relations of the College of Medicine at Newcastle-on-Tyne to the University of Durham.

LAST week I alluded to the relations existing between the College of Medicine of Newcastle and the University of Durham, but a few more words as to the College will be in place. The College is an incorporated society registered under the Companies Acts. It is governed by the "Members" and the Council, the Council being elected by the "Members." There are 11 "Members" of the College, all of whom are engaged in the practice of medicine and all, with one exception, occupy a position on the teaching staff of the College. The "Members" are the ultimate authority under the articles of association and receive their remuneration for their services as teachers in the College out of the surplus of receipts over expenditure for the year. This surplus varies from year to year and consequently the remuneration of the "Members" also varies. It is this payment of "Members" out of the annual surplus which is the objectionable feature in the present constitution. The "Members," it is argued, and reasonably so, should receive a fixed remuneration for their services in the same way as the remainder of the teaching staff. For otherwise, the financial arrangements are bound to savour of the annual dividend order which the publication of a balance sheet does not dispel. And it is further obvious that so long as certain members of the teaching staff depend for their remuneration upon a surplus being realised and so long as the amount of remuneration depends upon the amount of the surplus so long will support from private individuals, public bodies, and Government be withheld. Division of profits can have no place in an educational institution which looks for external support. The best friends of the College have repeatedly and for a long time expressed the opinion that the "Membership" should be abolished and its place taken by some other form of government in which the division of the surplus among certain members of the teaching staff should be done away with. In the early days the existing arrangement was a perfectly sound one and, in fact, the only one possible, but those days have passed and new circumstances have arisen which require new methods. Whatever form of government the "Members" may think best, whether it be that they should aim at obtaining a Royal Charter or be content with something less, it is certainly urgent that some change in the direction indicated should be made, and that without delay. Once the "Membership" of the College is abolished and public control substituted the confidence of the public will be gained, with the result that public support will be forthcoming. And public support is badly needed at the present time for many purposes, but here one only need be mentioned—namely, funds to enable whole-time men to be appointed to the charge of the departments of physiology and pathology. The consideration of the provision of further facilities for teaching in these departments by the appointment of whole-time heads of the two departments is a matter requiring immediate attention from the College authorities. Physiology and pathology are subjects of such importance in the training of the present-day student of medicine that it is essential for them to be taught by men specially trained in these branches of learning, who will devote their whole time to their subject. At the moment the funds at the disposal of the authorities do not permit of this being done, but if the changes outlined above be made there can be no doubt that the money would be readily forthcoming, both for those and for other departments of the College.

The Infirmary and the College of Medicine.

Indications are not wanting of a tendency to separate the College from the infirmary in certain departments. It is essential for the best welfare of both institutions that the relation between them should be as close as possible. The connexion should, in fact, be so close that in certain departments the University teaching staff should be *ex-officio* members of the infirmary staff. When of the 13 professional members of the Council of the College nine are members of the infirmary staff and seven members of the house committee of the infirmary it should not be a difficult matter to come to some arrangement between the College and the infirmary whereby they will work together for the mutual benefit of both. It is inconceivable that certain subjects can be efficiently taught in the College, unless the material necessary for teaching purposes can be readily obtained from the infirmary and this is only possible when the two posts, the one at the College and the other at the infirmary in the same subject, are held by the same man.

A Correction.

In my letter published last week a paragraph reads: "The Council of the College of Medicine *has decided* to grant degrees in dental surgery ......"; whereas it should have read: "...... has decided *to recommend the Senate* to grant," &c. The resolution of the College of Medicine has been sent to the Senate but requires to be approved and passed by that body before the degrees can be instituted.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Cardiff Water-supply.

THE Cardiff corporation has for many years been fully alive to the importance of looking after the sanitary condition of the town. With commendable foresight an excellent supply of water was impounded many years ago in two reservoirs in the Taff Fawr Valley in Breconshire and the yield has been so plentiful that, except in the years 1887 and 1899, the supply has been quite sufficient for the needs of the inhabitants. The steady growth of the town has shown that the time has arrived for the construction of a third reservoir and a proposal is now being made to complete the works authorised as long ago as 1884. It is anticipated that the cost of this undertaking will be about £240,000 and will take some eight years to carry out. Apart from the anticipated needs of the town in the future the activity which has recently been shown by the Glamorgan county council in the direction of securing a general water-supply for the county has influenced the corporation in securing a further supply for the city while it is still available. Swansea and Merthyr

Memorial to Dr. Sidney Brice Smyth.

At a meeting of the friends and patients of the late Dr. Sidney Brice Smyth held in Belfast on June 23rd it was decided to raise a fund for the endowment of a cot in the Belfast Hospital for Sick Children as a fitting memorial of his life and the valuable work which he did in the hospital. An influential committee was formed and it was announced by the chairman at the conclusion of the meeting that the amount subscribed and promised up to date was £423, made up of sums varying from £25 to 2*s.*

British Medical Association: Ulster Branch.

At the thirtieth annual meeting of the Ulster branch of the British Medical Association held in Belfast on June 24th it was decided to ask the British Medical Association to hold its annual meeting in Belfast in 1909, and a general committee was appointed to make arrangements for this proposed meeting. Sir William Whitla has been nominated in the event as President-elect, and Dr. H. L. McKisack, Dr. Howard Stevenson, and Dr. C. E. Shaw as honorary secretaries.

The Belfast Hospital for Sick Children.

Dr. R. R. L. Leathem has been promoted to be physician to the Belfast Hospital for Sick Children and in his place Dr. James Colville has been elected assistant physician.

Birthday Honours.

The only Irish medical honour conferred on the present occasion is that of Dr. Peter O'Connell who is made a knight. He was for a time a member of the Belfast corporation and was elected by them as the first Roman Catholic high sheriff last year. He is surgeon to the Mater Infirmorum Hospital and a district surgeon to the police.

June 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Congress of French Medical Practitioners and the Reform of Medical Education in France.

THE Second Congress of French Medical Practitioners assembled at Lille on June 25th. The programme was a continuation of that which occupied the first meeting of the congress held in Paris last year, and included the reform of medical education, the freedom of the victims of industrial accidents to choose their medical attendant, and other matters. Last year's congress led to no practical results. A crowd of orators took the occasion to air a diversity of opinions in more or less violent language, with the result that the gathering, taking its tone from political meetings, came to resemble a somewhat rowdy trade union demonstration. However, the Government can no longer remain deaf to the oft-repeated complaint that the palpable defects in the official system of medical education are partly responsible for the discredit which has fallen upon the profession. On the other hand, so far back as June, 1905, the Minister of Public Instruction took the opinions of all the Faculties of medicine in the country as to what reforms were necessary, and in November, 1906, the Faculty of Medicine of Paris itself brought forward a complete scheme of reform. For this reason, immediately after the Practitioners' Congress in Paris, the Minister constituted an important commission to inquire into the reform of medical education. This body included professors, *agrégés*, and representatives of the medical associations. The commission sat for a year and ended its labours by presenting a long report compiled by Professor *agrégé* Teissier which appeared in my letter published in THE LANCET of May 16th last, p. 1449. It is thought that the Minister is waiting to deal with the report until the conclusion of the Practitioners' Congress, at which new motions were down for consideration. For some time past this question of the reform of medical education has been a fruitful cause of dispute. Dr. Roux, the director of the Pasteur Institute, which although independent of the Paris Faculty of Medicine exercises a very considerable influence, has published in *Le Temps* the text of a statement which he addressed to the Ministerial Commission to which I have alluded and of which he was a member. The commission did not support his conclusions and a great stir has been caused by their publication. He advocates the abolition of the system of *agrégé* professors, whom he would replace after the German model by *privat-docenten* with uncontrolled teaching powers who would be remunerated by their own pupils; these men would form a distinguished body of workers and the most successful teachers among them would be ultimately chosen for the chairs of the faculty after holding posts as assistant professors. It must be understood that this system finds most favour amongst the general body of medical men at the present day, for the existing machinery for the election of *agrégés* (*le concours d'agrégation*) has fallen into rank disfavour. Nobody is eligible for a professorship who has not passed a special examination, in which it is alleged that jobbery plays a considerable part, as in all medical examinations at the present time. These methods have had the effect of creating a privileged body, the members of which are elected without due regard to merit, and no man outside this ring can obtain an official post in the Faculty, however good a record of work he can show. It is contended that a body of *privat-docenten*, elected upon a more liberal basis regardless of persons, would prove infinitely more useful. Professor Bouchard has replied to Dr. Roux in another letter to *Le Temps*. It is an interesting contribution because it proclaims the principles controlling the guiding spirits of the faculty, which fully acknowledges that reforms are desirable provided that the existing state of affairs is allowed to remain unaltered. M. Bouchard thinks that the root of the whole matter is the Government's niggardly endowment of the Faculties, and he thinks the most urgent reform is the increase of the teaching staff and of its members' salaries. Speaking of the *agrégés*, he says that since their system of examination and admission was last revised the class of men who are elected differs very little from *privat-docenten*, since the examining body takes the candidates' original research work into its chief consideration. M. Bouchard gives the plainest proof that the faculty is not a fit body to reform itself, for it is in that very matter of the proper estimation of the merits of the candidates' work that the partiality of the jury is most apparent. If the second Practitioners' Congress starts anew a sufficiently energetic agitation in favour of abolishing the *agrégé* system it seems probable that the Minister will be obliged to act on it, and that the true reform of medical education, which in spite of the progress of the science of medince has undergone no change since 1823, will enter in a little time upon a new phase.

The Treatment of Vomiting in Tuberculous Patients.

At the Hospitals' Medical Society on June 19th M. Lion recorded his experiences with subnitrate of bismuth in the treatment of vomiting in tuberculous patients. He gives a morning dose of 20 grammes and has always found its administration for 12 consecutive days to be perfectly well tolerated. Good results are often apparent from its use from the first day, and the vomiting does not recur even after the administration has been discontinued. The treatment has no effect on the cough but when this is present it no longer causes vomiting and has another beneficial action in allaying the symptoms of painful dyspepsia. The only disadvantage which M. Lion has found from it has been the occurrence of a little diarrhœa in several cases.

State-Employed Workmen and the Campaign against Tuberculosis.

The Board of National Manufacturers, brought face to face with the constantly increasing ravages of tuberculosis in its workshops and factories, has hit upon the good idea of coöperating with the Association to Protect Children against Tuberculosis. This was founded by Professor Grancher and is presided over by Dr. Roux and concerns itself exclusively with prophylaxis, its method being to board out the healthy children of poor tuberculous persons in the families of country people. This saves the pocket of the patient and the health of his children. The adoption of these methods by the State Board of Manufacturers is a signal honour for the association.

Tuberculosis among Laundrymen.

On June 16th M. Landouzy communicated to the Academy of Medicine a capital study of the marked increase of tuberculosis among laundrymen, especially those living in the suburbs of Paris. He considers that these unfortunate men get infected from the linen of their Parisian clients; they then go into hospital, leaving their lodgings infected so that their successors contract the disease. Suresnes, Puteaux,

Forfarshire Medical Association.

A dinner was held on June 18th, Dr. A. Key of Montrose presiding. The guests included Professor J. Glaister of Glasgow and Dr. Angus Fraser of Aberdeen. Dr. Key, in his address, predicted the increase of small-pox owing to the numbers who took advantage of the "conscience clause," introduced, he said, by a facile Government at the bidding of a noisy lot of faddists. Dr. J. D. L. Macalister of Forfar was appointed President for the coming year.

Death of Dr. Andrew G. Dow.

Dr. Andrew G. Dow died at his residence, 26, South Tay-street, Dundee, on June 18th, after a brief illness.

June 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Auxiliary Lunatic Asylums for Ireland.

OUR county councils and boards of guardians are becoming every day more impressed with the necessity of making a wider provision for the victims of insanity and a more humane arrangement for the harmless lunatics who are now scattered through the various workhouses. After the passing of the Local Government Act the Roman Catholic Bishop of Ross pointed out to the Cork asylum committee that the incurable lunatic and the harmless pauper lunatic might be much more economically and, at the same time, humanely treated by the establishment of auxiliary asylums in the partially used workhouses or the workhouses that would be available if a proper amalgamation of unions took place, thus avoiding the expense of new and costly additions to the existing asylum buildings. This view of Dr. Kelly prevailed after some preliminary official resistance. The Youghal auxiliary was set up and it has satisfactorily realised the objects for which it was established. The same question is now being vigorously—even acutely—discussed in Clare county. There are 444 inmates in the district asylum at Ennis, while the requisite sleeping accommodation is but for 373. There are about 250 insane inmates in the Clare workhouse; and, accordingly, provision is needed in this county for a total number of nearly 700. An estimate has been obtained of the cost of the additions to the existing asylum which the accommodation of the whole number would require. The calculated amount is £45,994 and the transference of the 250 pauper lunatics to the central asylum would involve a considerable addition to the annual outlay. In presence of these facts the county council has considered the question of following the Youghal precedent. It passed a resolution a year ago in favour of taking over the Tulla workhouse as an auxiliary asylum. This involved the amalgamation of the Tulla union with an adjoining one and the Local Government Board ordered an inquiry into the feasibility, &c. The results are embodied in a letter to the county council—a document which is highly deserving of the attention of the county councils and asylum authorities throughout Ireland. The only argument against the dissolution of the workhouse is the hardship to the sick inmates. This would be minimised by a proper ambulance. The report goes to show that there would be a great saving effected by the adoption of the plan, even to represent a total saving of practically £120,000 capital in a single county. This report and its sequelæ should have influence on the future arrangements for the insane throughout Ireland.

Dublin Dairy Yards and Slaughter-houses.

The public health committee of the Dublin corporation had before it at its last meeting the following report made by its veterinary inspector, Mr. Watson, M.R.C.V.S., on the subject of a statement made by a Dr. Greene of New York, in reference to the Dublin dairy yards:—

> In a recent statement made by a Dr. Greene of New York, he suggested that the milk of our city, owing to the dirty conditions of the yards, was probably mixed with excreta of animals. My inspections lead me to think that Dr. Greene employs the colours of "The Jungle" to draw attention to his statements. He visited, as far as I know, four dairy yards. The first, it is admitted, was irregular; it was not, however, at the time of our visit being used for dairy cows. There were about 30 cows in the yard, all of which were dry and fattening for beef. The proprietor of this yard milks 200 cows for his milk-supply. These were away on grass on the occasion referred to. There was a milk store in connexion with the yard, which was scrupulously clean. The other yards did not call for any comment as to want of cleanliness or order; but in one, our American friend seriously criticised the architecture of the cow-house or shed, and I do not join issue with him, for it was an uncomely structure, but no matter how inartistic, if a shed is ample in air-space, light, and ventilation, and attention is paid to cleanliness, the milk-supply is not likely thereby to be contaminated, and that is my chief concern.

On June 27th four summonses were heard at the suit of the corporation against butchers for the use and occupation of private slaughter-houses. According to Mr. T. M. Healy, who defended the butchers, the corporation was trying in an unfair way to compel butchers to resort to the municipal abattoir, and the arguments of the defence prevailed, the summonses being dismissed in two cases and withdrawn in two cases, but the corporation received its costs.

Tuberculosis Exhibition Opened in Wicklow.

The Tuberculosis Exhibition was opened on June 23rd by the Countess of Aberdeen, who was accompanied by Sir W. J. Thompson. In the course of the proceedings enthusiastic promises of support to Lady Aberdeen's propaganda were made by the various speakers, one of whom, Mr. James Girnon, a member of the urban district council, made a most important speech. He stated that to his mind there were others besides the common people who wanted to be educated into a sense of the responsibilities which they owed to the country and the people. In this connexion he meant the responsible boards which were intrusted with the government of the country, and in the forefront of these he would place the Board of National Education. If the same neglect of the material wants of the young prevailed in any degree throughout the country as obtained in Wicklow it was no wonder that consumption spread throughout the land. The national school in Wicklow was condemned as insanitary 14 years ago by an inspector of the National Board, but from that day to this the National Board and the Board of Works had failed to carry out the building of the new schools. Until these boards were made amenable to the force of public opinion the health, education, and material interests of the people would be neglected. A local branch of the Women's Health Association was then formed, all the prominent ladies of the town and neighbouring district becoming members.

Report of the Veterinary Surgeon to Belfast Corporation.

The first annual report of Mr. J. A. Jordan, veterinary surgeon to the corporation of the city of Belfast, for the year ending April 30th, 1908, has just been published and is a very interesting document. He points out how unsatisfactory inspections of carcasses are (especially outside the city boundary) without the viscera, particularly in the case of tuberculosis. There are seven licensed private slaughter-houses in Belfast and three for the slaughter of swine, where, on an average, about 3000 cattle, 4250 sheep, and 7979 swine are annually slaughtered. It is curious that for the past ten years not a single seizure has been recorded. Mr. Jordan wisely advocates abolishing all such licences. There is one knackery in Belfast where about 500 horses are killed each year. Mr. Jordan is against any additional licences for such places being granted. As to pork, he recommends the establishment of a meat inspection depôt at each of the railway termini, through which all meat coming into the city by rail would have to pass, that coming by road to be taken directly to the inspection station. It is scandalous that pork not inspected in country districts finds its way into Belfast as bacon. In the Belfast pork market 18,330 carcasses were examined in the year, and of these three were wholly condemned, and 274 were passed after removal of diseased glands for tuberculosis; four were wholly condemned for other causes. During the year 57,956 animals (cattle, calves, sheep, goats, deer) were slaughtered at the abattoir, and of these 521 carcasses were partially or totally destroyed as being unfit for food. A certificate is given condemning the site of the existing Belfast abattoir signed by Dr. J. McCaw, president, Ulster Medical Society, Dr. C. J. Clibborn, Local Government Board Inspector, and Mr. H. W. Bailie, medical officer of health. In reference to suitable *sites* for the new abattoir Mr. Jordan recommends the present horse fair. A good regulation in Belfast is that all meat killed outside the city and brought into the city for sale must, before being sold or exposed for sale, be brought into the inspection station. A series of appendices are attached to an admirable report.

her life because she was subject to epileptic fits, which constantly lost her her situations. She had taken at different times phosphorus and caustic potash, and finally she resorted to swallowing pins. The last attempt consisted in swallowing two open safety-pins and five hairpins. Soon afterwards she complained of intense gastric pain with general debility. Her story was doubted, as x ray examination and prolonged careful search of the fæces showed no trace of a foreign body in her alimentary canal. Her mental condition necessitated her detention in the insane ward. Here she developed symptoms of septicæmia and an empyema of the right side was found. An operation was performed (resection of the rib and evacuation of the pus) but the patient gradually sank and died. The necropsy showed the following conditions. There were multiple abscesses of the brain, both lungs, and the spleen, in addition to a subphrenic abscess and a pleural empyema which communicated with each other by a hole in the diaphragm of the size of a half-a-crown piece. The point of a pin was felt in the left lobe of the liver, where it was bound down by firm adhesions to the stomach. This organ was then opened and its mucous membrane was found covered with small old hæmorrhages. Next to the pylorus the blunt end of a pin was visible. Its point was the object felt through the liver. The pin was about four inches long, similar to a hat-pin. In the lowest portion of the descending colon was an accumulation of scybala, and in them were found numerous similar pins and needles, together with a few hairpins. The entire ileum, jejunum, and part of the colon showed numerous small hæmorrhages, and in the cæcum several small abscesses of the intestinal walls were found. There were many adhesions between the intestines and the abdominal walls, generally at the site of perforations of the gut. The pins had all travelled down the alimentary canal except one which had become lodged in the stomach and liver. Two and a half years had elapsed since the first attempt to swallow needles, and it is very likely that none had left the body *per vias naturales.*

The Operation for Cancer of the Penis from a Modern View.

Docent Dr. Föderl at a recent meeting of the Gesellschaft der Aerzte showed a patient who had suffered from an ulcerated tumour of the penis a year and a half ago. He also showed the parts which were then removed from him. Dr. Föderl operated on the same principles as are followed in the operation for cancer of the mamma—namely, complete removal of the cancer and of the glands, if possible with the fat. He began by making a horizontal incision above the symphysis pubis, curving it both ways so that all the inguinal glands on both sides were easily extirpated. When the middle line was reached the incision was carried down to the penis, and then an oval incision around the penis was made. The urethra was isolated so that it could be implanted into the perineum, the corpora cavernosa were secured between ligatures and the root of the penis was then divided, whilst the dorsal lymph vessels, the glans, the cavernous bodies and the penis minus the urethra were removed *en bloc*. The experience of surgeons shows that even if the carcinoma has been situated at the glans itself a deep amputation of the penis is soon followed by a recurrence, or rather by what ought to be termed local metastasis in the scar, due to a lymphatic carcinomatous infection of the dorsal lymph vessels, which occurs very quickly. Malignant tumours of the penis must be dealt with in the same way as cancer in any other organ. The result of the operation was very good (freedom from recurrence for a year and a half at present). The patient has fair control over his urethra, which was implanted near the anus.

Vienna, June 27th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Scientific Research in India.

THINGS are happily very much changed since the time when Ronald Ross uttered his exceedingly bitter cry as to the scientific medical research in India. Then a medical man in any of the public services who showed a bent towards original investigation was regarded suspiciously as a crank. Such things must always be; the genius must be ahead of his times or where would genius find its opening? The main body of thought follows the pioneer but slowly; and yet it may be said that if the Imperial mills work slowly they certainly grind small. The inertia of a machine-like Government is enormous and it takes time to set it in motion; once in action, however, the results are usually thorough. A satisfactory proof of this is afforded by the report of the Advisory Committee for the Tropical Diseases Research Fund for 1907. The committee was formed in 1904 and consists of members whose names are the best guarantee for efficiency and enlightenment. The death of Sir M. Foster made a serious breach in its ranks, but his place has been filled worthily by Dr. J. Rose Bradford. The funds at the disposal of the committee for the year under report amounted to £3075. The functions of the committee are to administer such funds to the best advantage and to collect and publish the reports of the various research laboratories. The committee further advises Government on questions of tropical hygiene and keeps in touch with the various workers, and while in no wise hampering originality suggests lines of activity and affords assistance and advice. The present report embodies a very large and important mass of original work. The campaign against tropical diseases has been fairly opened all along the line. Every parasitic enemy of the human race now finds a group of specialists opposed to it. New titles are bestowed on the leaders. We read, for instance, of a professor of helminthology, of a protozoologist, and of an arthropodologist, who, by the way, is Lieutenant-Colonel A. W. Alcock, I.M.S., so well known as a naturalist in India. Naturally the committee complains that the funds are insufficient for all it would like to do. Nevertheless the beginning is very good and the rest will come. Reports are to hand from every corner of the world —British Guiana, Ceylon, the Malay States, Africa, the West Indies, the Straits Settlements—all send their quota, and the success already obtained is real and important.

Sanitary Reform in Bengal.

The committee of the Calcutta Trades Association has addressed the Secretary to the Government of Bengal, Municipal Department, in terms of approval of the proposed improvement of the sanitary services in India. The committee of the association observed that the sanitary boards which it is proposed to establish are in addition to certain officials to include in their number one or two non-officials who are to be natives of India. The committee considers that while it is desirable to have the non-official community represented on these boards it would be a grave mistake in the case of many towns and cities to exclude European non-officials. In regard to the staff of medical officers of health in this country the committee is in entire accord with the suggestion that its hands should be strengthened. The committee of the association also supports the suggestion that a special European officer of health should be allotted to every town with a population of 100,000 and that for every additional 100,000 inhabitants there should be an additional European assistant health officer.

Cholera and the Mohmand Field Force.

Owing to the outbreak of cholera among the troops several changes in regiments forming the first three brigades had to be made almost at the eleventh hour. The Northumberland Fusiliers, originally in the 1st Brigade, have not been able to take their place in their brigade. A few cases of cholera occurred among them, but the latest reports fortunately show that they are now free from cases. The Guides Infantry, who returned from Landi Kotal with cholera, have also been prevented from going. Their place was to have been taken by the 4th Gurkhas, but the latter regiment, which was railed to Peshawar from Abbottabad, arrived with three cases of cholera and shortly after developed two more. Their place was accordingly taken by the 19th Punjabis from the 4th Brigade. The most serious outbreak has, however, occurred among the Munster Fusiliers, as I mentioned in my last letter. It has prevented that gallant regiment from taking any part in the expedition. Fortunately the mortality has been unusually low, and it is now hoped that the worst is over. The West Yorkshire Regiment, which arrived from Nowshara almost at the same time as the 4th Gurkhas, marched out at once to Shabkadr. Several of the units infected with cholera are in camp near Haraina, about ten and Billancourt have become in this manner veritable hotbeds of tuberculosis. The only remedy is to insist upon the disinfection of the linen of tuberculous patients, and to effect this the notification of the disease is necessary. Unfortunately notification and the consequent disinfection subject the unfortunate patients to absolute persecution, for landlords and hotel proprietors alike give them notice to quit. But the danger to the rest of the community is becoming so serious that notification seems more and more to be a necessary evil. M. Lereboullet supported M. Landouzy's contention and so did M. Lancereaux, though he said that it was necessary to be quite clear as to the rôle played by alcohol in the etiology of tuberculosis amongst laundry workers, for many employers paid their workpeople, both men and women, in alcohol, or even kept a canteen in their establishment.

The Radio-activity of Thermal Springs.

It is a recognised fact that the therapeutic properties of warm springs are partly due to their radio-activity. On June 22nd M. Armand Gautier communicated to the Academy of Sciences a note by M. Garrigou who has recently demonstrated in a fresh manner the reality of this phenomenon as far as it concerns the warm springs of the Pyrenees. To do this he employed an ingenious photographic method. He inclosed a sensitive film in a hermetically sealed aluminium tube and immersed it into the water of the spring, with the result that the film was affected by the rays. When the experiment was repeated with a leaden tube, which is impermeable to the radium emanations, no impression was produced on the film. It stands to reason that in performing the first experiment the greater the radio-activity of the water the quicker the effect will be produced.

The Photography of Sounds.

M. Poincarré presented to the Academy of Sciences on June 22nd the results of researches upon the "photography of sounds" by MM. Georges and Gustave Laudet. These investigators, whose method is one of intensive reconstruction of speech by a mechanical device, have not before made public their photographic sound-records. The photographs which were shown at the Academy are remarkably clear and allow the phenomena of phonation to be analysed in a way hitherto unthought of. The smallest details of vocalisation, lisping, and breathing are exquisitely reproduced and vibrations are recorded of no greater range than 1-50000th of a millimetre.

Projected Visit of French Medical Men to London.

A visit of French medical men to London and the Franco-British Exhibition has been arranged at the invitation of the staff of the French Hospital in London, by one of its members, Dr. Leonard Williams, and other English medical men, with the assistance of Dr. Heuzé of Paris. The object of the trip will be to explore London with the greatest possible comfort and it will be less of a scientific expedition than an outing for medical men interested in all the arts. The party will leave Paris on Sunday, July 12th, and will return on the following Sunday evening; its members will have the opportunity of visiting the hospitals in the morning and will spend the afternoons in seeing the museums and public buildings. They will be "personally conducted" by a guide speaking French. The medical men who go will be able to take their wives and children, and the total expenses will not exceed 250 francs for each person. Dr. Heuzé, 10, Rue de St. Petersburg, Paris, will supply all information concerning the trip.

June 29th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The Zürich Sanatorium for Consumptives.

THE ninth annual report of the sanatorium for poor consumptives of the Canton of Zürich, which is situated in the hills above Wald, has just been issued and contains some interesting details. During the last year 143 men and 159 women were treated, of whom 273 were suffering from consumption. The average stay was 139 days. 46 per cent. were in the first, 17 per cent. in the second, and 37 in the third stage (according to Dr. Turban's classification). 84 per cent., the usual percentage, were discharged in an improved condition, 70 per cent. being fully fit for work. The medical director, Dr. Staub, has made a very careful investigation with regard to patients under treatment at Wald during the years 1899 to 1905 and received answers from 90 per cent. of the patients. Dr. Staub has grouped them according to the stage of their disease. Of the patients treated in the sanatorium during the first stage 84 to 72 per cent. were still fit for work after periods varying from two to eight years, the percentage of the patients for 1899 being as high as 89. Of the patients in the second stage 53 to 31 per cent. were capable of undertaking their usual work; of those in the third stage only 33, 26, 24, 14, 24, 10, and 5 per cent. in the respective years. We thus have the clearest of evidence to show that for effective treatment patients should be sent to a sanatorium when in the first stage. A new wing is being built to receive children and £4000 towards the cost of £9000 necessary for the purpose was raised at a bazaar held in Zürich last year.

Cancer of the Uterus in Switzerland.

Cancer of the uterus causes about 300 deaths per year, or 99 per 1,000,000 inhabitants, in Switzerland. The number of deaths in the 30 years from 1876 to 1906 has increased from 2102 to 2136 and 2343 per decade, the total being 6581 deaths in 30 years. There has been no actual increase but a slight decrease, as the population is greater. The average age at death is 56 years. Statistics show that 8·15 per cent. of all fatal cancers (which numbered 37,387 in 30 years) are uterine and 16·49 of all fatal cancers occurring in women are uterine.

Zürich, June 23rd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Professor Erben on Ataxy.

A VERY interesting lecture on ataxy was delivered before the Medical Society in Vienna by Professor Erben in which he raised several new points as regards the physiological explanation of the condition. All experiments have shown the fact that equilibrium is maintained only by coöperation of three factors—the muscles, the joints, and the soles of the feet. The last are sensitive to all changes in the equilibrium of the body and give information as to whether the main weight of the body is projected towards the heel or the great toe in sagittal direction. The normal individual experiences variations of equilibrium of the whole mass of the body, but besides this the tabetic patient experiences also spontaneous movements of the joints which account for his abnormal swaying. These spontaneous movements of the joints are very important; they are often underrated in their effect. They are to be accounted for by loss or diminution of the deep sensibility of the affected joints. They appear only on voluntary muscular effort and disappear in joints where there is no active contraction of the muscles. They can be overcome by strenuous muscular effort and it is for this reason that many tabetic patients exhibit the peculiar striding gait, the powerful contraction of the flexor and extensor cruris muscles freeing the knee and the joints of the foot from their spontaneous movements. If a tabetic patient is allowed to touch the wall with one finger whilst he is being tested for Romberg's sign he still sways but does not lose his balance; the finger is insufficient to stop the involuntary movements of the joints. If an ataxic patient is made to stand with his legs wide apart and his eyes closed then an opinion may be obtained as regards his loss of plantar sensibility. If it is only slightly impaired very slight swaying is observed, mostly backwards and forwards. A lateral swaying shows that his deep sensation is much impaired and he can no more differentiate whether his right or left foot is bearing the main weight. If lateral swaying appears only when the base is narrowed by bringing the soles nearer to each other, it indicates that sensibility on one side is markedly diminished. Spontaneous movements of the joints are not pathognomonic for tabes, for they have been observed in various disturbances of sensibility of both cerebral and peripheral origin.

A Fatal Case of Pin-Swallowing.

A recent post-mortem examination of a girl, aged 20 years, who had succumbed to a protracted illness diagnosed as septicæmia, revealed some very interesting facts. The girl, who was a domestic servant, had been sent to hospital as she had attempted on several occasions to destroy

miles from Peshawar, along the Shabkadr Road, the remainder being in the vicinity of Shabkadr and Mutti Moghal Khel. As far as Peshawar city is concerned there are now few cases of cholera occurring, and every precaution is being taken both in the city and the cantonment to prevent any spread of the disease.

Cholera and Plague in Calcutta.

Calcutta was spared a cholera epidemic during the late Ardhodaya Jog festival, thanks to the precautions of its sanitary services, but the disease made its appearance some time later and is now raging in the city, but is confined chiefly to its northern half. The outbreak, according to the municipal health authorities, is not so intense in its severity as that of January, 1907, but seems to be part of an epidemic extending over a large part of Bengal. It is probably associated with the lowness of the water in the Hooghly, which is found on analysis to be more than usually contaminated at the present time. On the other hand, so far as the plague scourge is concerned, it is satisfactory to learn that the outbreak this year proves to be very limited in extent. We have arrived at what is usually the period for the height of the plague mortality, but the returns for the last two weeks show that the numbers of deaths daily do not amount to even half of what they were at this time last year.

New Standard Plan for Barracks.

The new barracks for British infantry which have recently been built by the Military Works Services at Jubbulpur, Ahmednagar, and Quetta are a great improvement on the old form and will serve as a model for all future buildings of this character in this country. In the past the general practice was to build barracks in the form of a cross, in the two ends of which were the dormitories with the dining-rooms, &c., across the centre. Under this arrangement the cook-house was placed at some considerable distance from the dining-rooms, so that not only did the food arrive cold but the kitchen itself was not under proper supervision. Under the new system of building four dormitory blocks are placed at the corners of a parallelogram, each dormitory accommodating a half company. In the middle of the parallelogram there stands a long building, in the centre of which are placed the two kitchens and at each end are the dining-rooms, each of which accommodates one company. The dinners are served through a hatch connecting the dining-rooms with the kitchens and arrive hot, while the kitchens themselves can be looked after in a most satisfactory manner. The kitchens will be equipped with Warren's cookers in place of the old smoky "chulas," while the dining-rooms will be provided with fly-proof doors and windows.

Tour of an American Man of Science.

Dr. G. A. Dorsery, American ethnologist, curator of the anthropological section of the Field Columbian Museum, Chicago, is visiting Darjeeling, Assam, Chota Nagpur, Madras, and Ootacamund to see various hill tribes. He thence journeys through South India, crosses to Colombo in Ceylon, and will subsequently proceed to Sumatra, Java, Celebes, and Borneo. When his work there is completed he expects to make a long stay in the Philippines where three of his assistants are working. He will then return to America.

Wild Animals in the Central Provinces.

In the Central Provinces human mortality caused by wild animals has decreased. Tigers, however, claimed more than a fair percentage of the mortality. In Chanda there were 21 such fatalities. There are said to be three man-eaters in Baihar Tahsil. A case is reported where a Gond was mauled by a tiger and rescued by a band of villagers and then snatched away from the rescuing party on its way home. The destruction of a man-eater panther in the Panabaras Zamindari brought about a decrease in deaths in the vicinity. Snakes killed 996 persons, which is reported as being the lowest figure returned in any one of the last seven years. Experiments are still proceeding with the Lauder Brunton treatment of snake-bite by incision and application of permanganate of potassium. There is an increase of about 1000 in cattle mortality, tigers being credited with most of the kills, with panthers a good second, and then wolves. The reward for the slaying of panthers has now been increased to Rs. 25.

May 21st.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Royal Prince Alfred Hospital.

THE twenty-fifth annual meeting of the governors of the Royal Prince Alfred Hospital, Sydney, was held on April 27th, His Excellency Sir Harry Rawson, the State Governor, presiding. Professor Anderson Stuart, the chairman of the hospital board, read the annual report. The number of in-patients treated was 4553 and the number of operations was 5 per cent. higher than the previous year. The new department for therapeutic inoculation was hardly in full swing but promised good results as an adjunct in the treatment of disease. An important amendment of the by-laws permits senior members of the staff to serve 18 years instead of 12 as formerly, and every member of the medical staff must retire at 60 instead of 65. He claimed that no more complete operating facilities existed in any part of the world than those provided by the new theatres at the hospital.

Hospital Saturday.

The annual collection in aid of the Sydney hospitals was taken on May 2nd and the streets were invaded by lady collectors who "held up" every passer by. The effort was remarkably successful, a sum of £6380 being realised. Over 10,000 more coins were received than on the last occasion; they consisted of 13 sovereigns, 46 half-sovereigns, 347 half-crowns, 230 florins, 1286 shillings, 7687 sixpences, 4209 threepenny-pieces, 58,983 pence, and 37,512 halfpence. Altogether four and a half tons of copper coins were collected.

Melbourne Milk-supply.

The present season is the driest that Victoria has experienced for many years and pasturage is very deficient, with the result that starving stock are being deported to New South Wales. The *Argus* has recently raised the question that the visible supply of milk is insufficient in the metropolitan area and that extensive adulteration must exist in order to make up the shortage. Leading dairymen, while not prepared to admit that adulteration is practised to the extent that the *Argus* figures indicate, agree that it would be a good thing at the present time to encourage a much stricter inspection so that offenders may be caught. The estimate referred to was that the daily consumption of milk in Melbourne was 5425 gallons more than would be accounted for by the milk produced in, or forwarded to, the city. Mr. Cameron, head of the dairy supervision branch of the Agricultural Department, in a newspaper interview, stated he thought it would be unreasonable to say that the whole of an apparent shortage was made up by adulteration. The price of milk had advanced from *4d.* to *5d.* per quart and probably less milk would in these circumstances be consumed. He further said, "I feel satisfied that milk cannot be obtained from sound healthy cows under wholesome and sanitary conditions and be distributed by the present expensive methods at a reasonable business profit for a price of less than *4d.* per quart in normal times." A point emphasised by Mr. Cameron was the wasteful method of distribution. "A street containing 50 houses," he said, "will under present conditions be visited by five or possibly ten different milk carts, all of which are practically doing the same work." Medical men have also taken the matter in hand, for a special meeting of the Victorian branch of the British Medical Association was held on May 2nd to consider the milk-supply of Melbourne in relation to the prevention of infantile mortality. Lady Talbot had been much interested in the matter and at the request of the council the meeting was attended by His Excellency Sir Reginald Talbot, the State Governor, and Lady Talbot. The principal motion was proposed by Dr. J. W. Barrett and was as follows:—

> That this meeting approves of the establishment of a small milk-supply for educational purposes.

The following scheme was suggested:—

> (*a*) That milk shall be obtained from an approved dairy or dairies specially inspected by the Agricultural Department and shall be rapidly conveyed to the bacteriological laboratory of the university; (*b*) that the milk be then pasteurised or refrigerated or otherwise treated by approved methods; (*c*) that the milk so treated be distributed in

sterilised bottles to the Women's Hospital, the Children's Hospital, and the various crèches, and if there be a surplus to such approved people as may desire to have it; (*d*) that the treatment of the milk be under the general supervision of a small committee of medical men, including Dr. Bull, the director of the laboratory.

This was seconded by Dr. J. W. Dunbar Hooper who recently attended the International Congress at Brussels and presented a report on Infantile Mortality to the Federal Government specially recommending the adoption of some measures resembling those in force at such institutions as the "Gouttes de Lait." A committee consisting of Dr. Hooper, Dr. Jeffreys Wood, Dr. Cole, Dr. W. A. Wood, Dr. Argyle, and Dr. Bull was appointed and it was also decided to ask Dr. Norris, Chairman of the Board of Public Health; Dr. Cherry, Director of Agriculture; and Dr. Jamieson, city health officer, to act if they were willing. The committee has already held an initial meeting at which Lady Talbot was present. The question of finance appeared more difficult than was at first supposed and it is probable that the Government will be approached with a request for assistance.

Medical Man Killed.

A sad accident occurred near Traralgon, in Victoria, by which Dr. R. H. Horne lost his life. Dr. Horne, in company with his wife and a lady friend, were returning home in a motor-car, and on approaching a bridge it is supposed the steering gear became disarranged. The car collided violently with a fence and all the occupants were thrown out. Dr. Horne was seen to be severely injured and was conveyed to his house, where he died on the following day from internal injuries. The late Dr. Horne had a strongly adventurous personality. He served with Cameron's Scouts as a private in the South African War and was severely wounded through the lung. He recovered and returned to the war after being invalided home. Subsequently he travelled in China with an insurance agent and was stoned by a mob. For this the Chinese Government paid him £1000 damages. He then bought a practice at Traralgon where he has since resided.

A Cancer "Cure."

Some two or three years ago Sir John Madden, the chief justice of Victoria, startled the community by speaking and writing very strongly in favour of one Davis who for years has claimed to cure cancer by means of a special application of his own. This action was the more dramatic because "Professor" Davis has on more than one occasion attracted the attention of the Crown law authorities in connexion with the death of patients while under his treatment. The matter was brought under the notice of the Premier and a board was appointed to inquire into the alleged efficacy of Davis's "cure." The constitution of the board was partly professional and partly political. It was made up of Dr. Norris (Chairman of Board of Public Health), Mr. R. Hamilton Russell (surgeon to Alfred Hospital), Dr. Mollison (pathologist to Melbourne Hospital), Dr. Cherry (Director of Agriculture), and Mr. Duncan Turner, with Messrs. Edgar, Watt, Boyd, McBride, and Britters. The evidence taken was principally from patients of Davis. The board has presented an interim report signed by all the members except Mr. Turner. The report states that the substance employed is a caustic and destroys the tissues with which it is in contact. There was no evidence to show it possessed any selective action and no evidence to show that, as claimed, it was in any way unique or different from old and almost discarded agents of like nature. Although Davis denies that his preparation contains arsenic he does not deny that arsenic has been found in a series of post-mortem examinations in the tissues of patients who have died under his treatment. He offers no explanation except that it may be produced by decomposition. This the board rejects as absurd. None of the cases diagnosed as cancer by the medical members of the board before treatment by Davis have so far been successfully treated; and the same applies to the cases presented while under treatment and recognised unequivocally as malignant. There were five such cases and three have since died. Mr. Turner signs a dissenting report, in which he thinks that there is evidence of a selective action in Davis's remedy and that the report is generally unfair to Davis. The board has adjourned for six months in order to allow time for observation of cases now under treatment by Davis.

May 30th.

Obituary.

BERTRAM LOUIS ABRAHAMS, M.B., B.Sc. LOND., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO WESTMINSTER HOSPITAL; JOINT LECTURER ON MEDICINE AT WESTMINSTER HOSPITAL MEDICAL SCHOOL, ETC.

THE painfully unexpected announcement of Dr. Bertram Abrahams's death upon June 21st has caused a truly deep regret amongst his circle of acquaintance, whilst to those of a closer intimacy his decease is indeed an affliction, made only more grievous by its occurrence at a time when the worthy reward of unremitting hard work was well within his grasp. Dr. Abrahams was the only son of Mr. L. B. Abrahams, head-master of the Jews' Free School in Spitalfields, and like his father took the keenest interest in the social welfare of his community. He was born in 1870 and received his education at the City of London and University College schools, from which he entered University College for his medical training. He was a brilliant student from the first, obtaining triple distinction as exhibitioner, scholar, and gold medallist in his college, where he obtained the posts of demonstrator of anatomy and physiology. At the University of London he fulfilled the promise of his class work, gaining fresh laurels with each examination, which included first-class honours at matriculation and at the intermediate examinations for science and medicine, whilst he took his B.Sc. degree in 1890 by an examination that won him similar honours and the University scholarship in physiology. Five years later he became Bachelor of Medicine at the University of London, with honours in medicine and forensic medicine, after he had visited the continent for further study. He then held the post of house physician in his own hospital and in 1896 became a Member of the Royal College of Physicians of London, his Fellowship following in 1904, when he became an examiner in physiology to the Conjoint Board. Westminster is the hospital which mourns him especially, for he was appointed medical registrar there in 1899 and since that time has done splendid teaching work in its school as lecturer in physiology, pathologist, sub-Dean, lecturer in medicine, and assistant physician to the hospital. He was chosen Arris and Gale lecturer by the Royal College of Surgeons of England in 1906-07.

Dr. Abrahams excelled as a teacher and was one of the most successful tutors in London, for he had the right love of his work and a clear method of imparting his knowledge that rendered the most difficult subjects straightforward to his pupils. It is not surprising that a man who took such pains with the students of his hospital began to reap his reward in an increasing consulting practice at a comparatively early age, and both in his hospital and private work his opinion upon a case of difficulty repeatedly justified the confidence that was placed in it. He was a man of wide interests outside medicine, a prominent Freemason, and an enthusiastic cricketer. In the craft he was a P.G.J.W. of Surrey, and his love for athletics was testified by his interest in the Jewish Lads' Brigade, which he took an active share in founding; he attended its summer camp for many years as principal medical officer. He was at one time medical inspector of schools to the London County Council. The name of his friends was legion, for he had an attractive manner and a sense of humour.

Dr. Abrahams's most important contributions to literature were his articles in Allchin's "System of Medicine" on Myalgia, Myositis Ossificans, Medical Applications of Electricity, and Diseases of the Mouth, Pharynx, and Œsophagus; his contributions to the "Medical Annual" and to periodicals included work on Rheumatism, Chorea, and Diseases of Metabolism. He was a member of the principal English medical societies, and several of his studies are included in the Transactions of the Clinical Society in 1898 to 1899. There is no doubt that his devotion to work overtaxed his strength and hastened his death which was due to kidney trouble. The knowledge of this complaint had sent him to Egypt for several winters past. 12 years ago he married the only daughter of Mr. A. J. Simmons, who survives him with a daughter, their only child.

Sir William H. Allchin writes: "My acquaintance with the late Dr. Abrahams dates from the year 1899 when he was appointed as medical registrar at the Westminster Hospital. It was soon evident that the brilliant record of academic success, both at the University and at University College, with which he came to us was fully justified, for he at once took his place amongst us as a physician whose knowledge was based upon the soundest and most recent physiological and pathological principles, which his inborn ability and clinical acumen had developed and applied. And so his professional reputation remained with us to the end. But there was a good deal more to be said of Abrahams than that he was a good and able physician. He was a good and able all-round man. To the thorough understanding of the fundamentals of the science and art he was pursuing he added an exceptional power of imparting to others the knowledge he possessed; and this in the clearest language, whether written or spoken. He thus possessed all the essentials for a successful teacher, and it is not going too far to say that for some years past a very considerable share of the medical teaching at the Westminster Hospital has devolved upon him. He liked it and threw himself into it with keenness, whilst a considerable gift of satire that was never unkindly added a zest to his instruction that served to hold the students' attention and gave interest to his remarks. His appointment as assistant physician to the hospital in 1903 increased his opportunities for teaching both in the out-patient room and in the school, and as one of the lecturers in the department of medicine he delivered a course on Applied Physiology, in which the perversions of physiological processes in disease generally were outlined, constituting a most valuable introduction to the subject of medicine proper. No one was more capable of doing this than Abrahams, and it is hoped that his lectures were left in a sufficiently prepared state for publication, as it is known was his intention. But there was something over and above Dr. Abrahams's ability as a physician and excellence as a teacher that endeared him to his colleagues and students and that made him at once so acceptable to most of those whose acquaintance with him was even but slight. There was a straightforward and clear-headed directness that induced a belief in him directly; there was no pettiness or self-interest in the way he regarded and dealt with the many questions upon which differences of opinion must of necessity exist among a number of men, combined though they be in the pursuit of a common purpose. His ready perception of the important points of any question at issue and the consistency with which he maintained his opinion when once it was formed rendered him an invaluable supporter to any cause he undertook, and made his advice sought for by many of his seniors, who knew that his actions might be relied on to back up his words and that whatever happened Abrahams would go straight and not fail him. The thoroughness with which he threw himself into whatever he undertook, whether it was the school cricket club or the Jewish Lads' Brigade, which he helped to found, or the graver questions of professional politics as they presented themselves at the College of Physicians, where though a Fellow of but a few years' standing he was already taking up a position, contributed in no small degree to the popularity of which his pleasant kindly manner laid the basis. No man is indispensable and few are they who cannot be replaced, but it is unlikely that for some time at least the niche that he has left in the entire community of the Westminster Hospital and School will be filled by one so many-sided, by so loyal a colleague and friend, and by so cordially esteemed a man as Bertram Abrahams."

THOMAS GARRETT HORDER, M.R.C.S. Eng., L.R.C.P. Edin.

We announced last week the death of Mr. T. Garrett Horder, a well-known and zealous worker in the cause of medical reform, which took place on June 15th at his residence at Cardiff. Mr. Horder, who was 70 years of age, received his education at the City of London School, whence he proceeded to the London Hospital and obtained the Membership of the Royal College of Surgeons of England in 1866. In 1873 he became a Licentiate of the Royal College of Physicians of Edinburgh and after acting as house surgeon and secretary to the National Sanatorium at Bournemouth he went to Cardiff, where he took an active interest in politics and greatly interested himself in municipal affairs. For many years he served on the school board, where he did good work by his advocacy of open-air recreation and gymnastic instruction for school-children. Though unsuccessful in his attempts to obtain a seat on the borough council (he fought three elections) he never ceased to work for the good of his borough. His great interest in general and municipal politics, however, did not detract from the keenness with which he endeavoured to uplift and to organise his own profession, as his various contributions to the columns of The Lancet and to the medical press generally sufficiently testify. As honorary secretary of the Hospital Reform Association he worked hard for the cause which he had so much at heart, and the address on Hospital Reform which he delivered before the Manchester Medico-Ethical Association some ten years ago[1] shows that he had a thorough grasp of his subject, though we were not always able to endorse all his suggestions for reform. He was an ex-President of the Cardiff Medical Society and a member of the council of the Medical Defence Union and joint honorary secretary of the Ethical Section of the British Medical Association. He was also public vaccinator for Cardiff. The deceased gentleman, whose death will be deeply lamented by all members of his profession no less than by his many lay admirers, was a brother of the Rev. W. Garrett Horder, the hymnologist, and leaves to mourn their loss a widow and one son.

Medical News.

University of Cambridge.—The following degrees were recently conferred:—

M.D.—R. E. Whitting, King's.

M.C.—E. H. Douty, King's.

M.B., B.C.—E. G. Fearnsides, Trinity Hall; E. B. Hinde, Emmanuel; R. C. Priest and K. D. Pringle, Gonville and Caius.

M.B.—J. H. B. Martin, Emmanuel; and S. L. Walker, Sidney Sussex.

B.C.—H. S. Berry and H. J. Cardew, Clare; J. B. Mennell, Pembroke; G. D. Alexander, R. Burgess, and H. N. Little, Gonville and Caius; J. B. Banister, Jesus; and J. F. Windsor, H. Selwyn.

At examinations for medical and surgical degrees (Easter term) the following candidates were successful:—

First Examination.

Part I., Chemistry and Physics (Elementary).—K. B. Aikman, Clare; C. S. Atkin, Caius; G. L. Attwater, Pembroke; J. Aydon, Clare; D. C. G. Ballingall, Emmanuel; H. A. Bell, Jesus; G. A. G. Bonser, St. John's; H. J. Bower, Emmanuel; E. C. Bradford, Pembroke; R. St. L. Brockman, Caius; A. E. Brown, Christ's; E. H. P. Brunton, Trinity; S. Butt, St. John's; R. N. B. Byatt, Clare; F. L. Cassidi, Corpus Christi; G. M. Chapman, Caius; W. H. W. Cheyne, Trinity; M. T. Clegg, Jesus; G. D. Compston, Trinity Hall; E. H. Copeman, Christ's; A. C. M. Coxon, Magdalen; H. E. Creswell, Caius; J. L. Crommelin-Brown and H. V. Deakin, Trinity; B. C. Ewens, Caius; E. Ezra, Peterhouse; W. D. Galloway, Clare; N. Garrard, Pembroke; N. Gray, Emmanuel; S. W. Green, Clare; J. R. Griffith, Christ's; H. G. Hooper, Emmanuel; B. L. Hutchence, Caius; C. O. Kerby, Trinity; G. C. King, Caius; C. Lambrinudi, Christ's; F. C. Lapage, King's; F. G. Lescher and G. A. Lilly, Caius; W. B. Loveless and L. A. McAfee, Pembroke; H. D. McCall, Christ's; H. Y. Mansfield, Emmanuel; J. A. Martin, Pembroke; C. F. Mayne, Caius; T. W. Melhuish, Pembroke; I. Mortada, Trinity Hall; W. New and N. F. Norman, Downing; H. G. Oliver and D. S. Page, Caius; A. A. Pallis, Trinity; C. F. Pedley, Jesus; R. A. Peters, A. C. Pickett, and S. G. Platts, Caius; E. L. K. Sargent, St. John's; C. J. Scholtz and D. N. Seth-Smith, Emmanuel; L. R. Shore and W. S. Sodden, St. John's; C. B. Spence, Pembroke; E. C. W. Starling, Jesus; R. J. Tweedy, Caius; C. F. Verrall, Trinity; P. Wallace, King's; and C. A. Weller, B. Whitehead, H. C. Whittall, and A. G. Williams, Caius.

Part II., Elementary Biology.—K. B. Aikman, Clare; S. G. Askey, St. John's; M. L. Atkinson, Emmanuel; J. Aydon, Clare; D. C. G. Ballingall, Emmanuel; P. H. Berry, King's; W. G. Bigger, Queen's; G. A. G. Bonser, St. John's; E. J. Boyd, Sidney Sussex; E. C. Bradford, Pembroke; J. C. Bramwell, Trinity; E. J. Y. Brash, St. John's; R. St. L. Brockman, Caius; A. E. Brown, Christ's; E. H. P. Brunton, Trinity; E. N. Butler, Clare; F. L. Cassidi, Corpus Christi; C. M. Chapman, Caius; W. H. W. Cheyne, Trinity; A. C. M. Coxon, Magdalen; E. D. D. Davies, Christ's; H. V. Deakin, Trinity; G. D. East, Emmanuel; B. C. Ewens, Caius; E. Ezra, Peterhouse; W. D. Galloway, Clare; N. Garrard, Pembroke; N. Gray, Emmanuel; J. R. Griffith and W. T. Hare, Christ's; A. D. Haydon, Caius; C. Helm, King's; G. J. Hill, Peterhouse; A. N. Hooper, Emmanuel; A. M. Humphry, Trinity; T. Jones, Sidney Sussex; F. G. Lescher, Caius; H. A. Lucas, B.A., Trinity; L. A. McAfee, Pembroke; H. D. McCall, Christ's; M. MacGregor and A. R. MacMullen, Caius; H. Y. Mansfield, Emmanuel; F. D. Marsh, Trinity; W. H. Marshall, Pembroke; C. F. Mayne and A. T. Miller, Caius; I. Mortada, Trinity Hall; R. F. S. Morton, Trinity; H. G. Oliver, Caius; P. R. T. Owen,

---

[1] The Lancet, Dec. 19th, 1896, p. 1742.

Christ's; D. S. Page, Caius; A. A. Pallis, Trinity; A. R. Panter, Clare; R. A. Peters and S. G. Platts, Caius; A. St. Johnston, Trinity; E. L. K. Sargent, St. John's; C. J. Scholtz and D. N. Seth-Smith, Emmanuel; J. E. Sharp, Caius; T. W. Sheldon, Emmanuel; L. R. Shore, W. S. Soden and G. W. Spencer, St. John's; E. C. W. Starling, Jesus; M. T. W. Steedman, Clare; H. M. Stephenson, Caius; A. V. Stocks, St. John's; W. J. F. Symons, Sidney Sussex; E. S. Taylor, King's; J. B. Thomson and J. M. Thorburn, Trinity; E. R. Thurston, Caius; C. F. Verrall, Trinity; P. Wallice, King's; C. A. Weller and B. Whitehead, Clare; and K. J. Yeo, Emmanuel.

SECOND EXAMINATION.

Human Anatomy and Physiology.—W. B. Alcock, Trinity Hall; L. A. P. Anderson, Emmanuel; G. V. Bakewell, Clare; H. G. Baynes, B.A., Trinity; C. H. Crawshaw, Christ's; J. Ellison, B.A., and G. V. Fiddian, Downing; J. P. Hill, M.A., Caius; R. S. Kennedy, Christ's; D. N. Macleod, Caius; O. de B. Marsh, B.A., Pembroke; W. M. Oakden, Peterhouse; T. H. Oliver and J. H. Pendered, Caius; M. J. Petty, Downing; P. W. Ransom, Pembroke; W. A. Russell, B.A., and C. M. Ryley, Emmanuel; F. B. Smith, King's; J. R. A. D. Todhunter, B.A., Caius; C. Worster-Drought, Downing; and C. R. Wright, Christ's.

THIRD EXAMINATION.

Part I. Pharmacology and General Pathology.—G. D. Alexander, B.A., Caius; H. L. Attwater, B.A., Pembroke; M. W. Baker, St. John's; J. B. Banister, M.A., Jesus; R. L. Barker, B.A., Caius; H. S. Berry, M.A., Clare; A. M. Boikin, B.A., and R. G. Canti, B.A., King's; H. J. Cardew, M.A., and H. T. Depree, B.A., Clare; E. St. G. S. Goodwin, B.A., Caius; R. H. P. Hick, B.A., Christ's; A. C. Jepson, B.A., Pembroke; K. T. Khong, St. John's; R. L. Ley, B.A., Pembroke; H. N. Little, B.A., Caius; E. Mellanby, B.A., Emmanuel; J. B. Mennell, M.A., Pembroke; G. Moore, B.A., Clare; P. A. Opie, B.A., Caius; W. M. Penny, B.A., Jesus; R. L. Rawlinson, B.A., Trinity; F. H. Robinson, B.A., Queens'; A. L. Sachs, M.A., Pembroke; F. P. Saunders, B.A., Clare; C. F. Searle, B.A., Pembroke; H. E. S. Stiven, B.A., F. R. Thornton, B.A., and G. B. Wainwright, B.A., Trinity; and M. H. Whiting, B.A., Downing.

TRINITY COLLEGE, DUBLIN.—At the Final Medical Examination held in Trinity Term the following candidates were successful:—

Part II., Medicine.—William H. M'Carthy, George B. M'Hutcheson, John L. Phibbs, Dixie P. Clement, David G. Madill, Richard P. Hadden, Alexander K. Cosgrave, Ernest C. Lambkin, John A. W. Panton, Samuel F. A. Charles, Gordon A. Jackson, Gerald G. Mecredy, James R. M'Causland, George Halpin, Thomas Ryan, Alfred H. Smith, and John C. Baker.

THE HOSPITAL OF ST. JOHN OF JERUSALEM.—On June 24th the Bishop of Gibraltar preached the anniversary sermon at the commemoration services of the Grand Priory of the Order of the Hospital of *St. John of Jerusalem* in England, held at St. John's Parish Church, Clerkenwell. After an inspection of the improvements in the recently restored ancient priory crypt of the church the annual general assembly of the members and associates was held at St. John's Gate.

STATE SANATORIUMS FOR CONSUMPTION.—The Grimsby union has been asking various boards of guardians in the West of England to pass a motion expressing the opinion that the State should provide district or county sanatoriums for consumption. The majority of the boards appear to have decided, as the Bridgwater guardians did at their meeting on June 24th, that as they had already provided a special place for the treatment of local cases of consumption there was no need to take any action in the matter.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The sixty-seventh annual meeting of this association will be held on July 23rd and 24th at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Dr. Charles A. Mercier. On July 23rd there will be a discussion on a proposition of Dr. D. G. Thomson:—

> That for the more efficient teaching and training of the coming generation of alienists in psychiatry the Medico-Psychological Association—in the first instance through its education committee—consider some scheme for post-graduate teaching and training, with or without the imprimatur of a diploma given after such a course (with or without examination) with a view to its being brought before the universities and other qualifying and teaching bodies.

On July 24th Dr. Robert Jones will initiate a discussion on "The Case against Dementia Præcox" and Dr. Lewis C. Bruce will introduce a discussion on Folie Circulaire and Manic-depressive Insanity—their Identity? and the Relation of the Depressed to the Elevated Stage; Dr. Alan McDougall will read a paper on the Principles of the Treatment of Epilepsy; and in the afternoon Lady Henry Somerset has consented to open a discussion on Some Aspects of Inebriety; Dr. Frank Ashby Elkins will read a paper entitled "Asylum Officials—is it necessary or advisable for so many to live on the premises?" and Dr. Horatio B. Donkin will give an account of the work of the Royal Commission on the Care and Control of the Feeble-minded. The annual dinner will take place on July 24th, in the Grand Hall, Criterion Restaurant, Piccadilly-circus, London, at 7 for 7.30 P.M.

THE League of St. Bartholomew's Hospital Nurses has sent a further sum of £500 towards the building fund of the proposed new Nurses' Home.

PROPOSED PUTNEY HOSPITAL.—The Duchess of Albany opened on the first, and the Duchess of Marlborough on the second day, a three days' bazaar at Putney last week in aid of the above hospital which is to be endowed under the will of the late Mr. Chester when built. Nearly £2300 were taken at the bazaar, which was very largely attended by the inhabitants of Putney who are anxious to have a hospital to supply the local needs of their rapidly growing district.

FATSHAN HOSPITAL, CHINA.—A new hospital in connexion with the Wesleyan Mission has been opened recently in Fatshan, Canton, South China, when Dr. W. J. Webb Anderson, the medical superintendent, conducted the dedicatory service. The new buildings consist of an out-patient hall, a block in which about 20 in-patients can be accommodated, two operating theatres, and nurses' quarters. The land occupied is about two and a half acres. The money to defray the cost of the hospital was raised almost entirely by Dr. Webb Anderson himself. There is a staff of five native Chinese female nurses. Native medical students who intend to qualify as medical missionaries receive their training in the hospital, afterwards proceeding to England to finish their education. Last year nearly 9000 paying patients were treated, besides a very large number of non-paying ones, and 355 operations were performed, so that the hospital may be said to have proved its utility from the beginning.

WEST LONDON HOSPITAL AND POST-GRADUATE COLLEGE.—The eleventh annual dinner of the West London Hospital and Post-Graduate College was held on June 23rd at the Empire Rooms, Trocadéro Restaurant, Piccadilly-circus, London, Mr. L. A. Bidwell, surgeon of the hospital and dean of the college, being in the chair. The hospital contains 160 beds; 2500 patients are treated in the hospital and over 34,000 new out-patients are seen annually. Post-graduate instruction has been given at the hospital since the year 1893 and 1339 medical men from all parts of the world have attended the classes. Of these 359 have been officers in the naval, army, and Indian medical services and 330 others have come from the colonies and foreign countries. The practice of the hospital is well adapted to the needs of medical officers of the Royal Navy and Royal Army Medical Corps and Indian Medical Service and the colonial services who have obtained leave for further professional study. Arrangements are made for all the necessary special classes required and the certificate of attendance at the college during such leave is recognised by the Admiralty, the War Office, and the India Office. The laboratory has been completely reorganised and placed in the hands of the pathologist, Dr. G. C. Low. The list of past and present members of the hospital numbers 1609. The toast of "The Imperial Forces" was proposed by Dr. H. J. Davis and was responded to by Inspector-General J. Porter, the Director-General of the Medical Department of the Royal Navy, who gratefully acknowledged the services rendered to naval medical officers by the West London Hospital Post-Graduate College. The toast was also spoken to by Surgeon-General Sir A. H. Keogh, the Director-General of the Army Medical Service, who said that by the sympathy of the medical profession there was now no dearth of candidates for the Army Medical Service; those applying were of high professional attainments and were also socially well qualified for the functions which they had to perform in the spheres allotted to them. He reminded his hearers that in time of war the whole medical profession must, and would, render assistance. The chairman proposed "The West London Hospital and the Post-Graduate College," and detailed the steps taken to secure success in post-graduate teaching. This toast was responded to by Mr. G. F. Marshall for the hospital and by Lieutenant-Colonel H. R. Woolbert, I.M.S., for the Post-Graduate College. To Dr. E. A. Saunders the toast of "The Visitors" was intrusted, and it was acknowledged by Sir Roper Partington. Mr. Aslett Baldwin proposed the health of the chairman, who suitably replied.

MEDICAL GOLFING SOCIETY.—This society held its annual tournament on June 18th at Guildford, by kind permission of the Guildford Golf Club. In Class I. (handicaps 12 and under) in the 18 holes match play *v.* Bogey, H. Tilley and D. Findlay tied with 2 up. In Class II. (handicaps over 12) F. J. Smith was first with 4 up and G. W. Dawson was second with 2 up. The scores for the best last 9 holes *v.* Bogey in the first class were H. Tilley 2 up, and D. Findlay, J. A. Willett, K. W. Goadby, and C. J. Marsh 1 up. In the second class the prize for the best last 9 holes *v.* Bogey was won by W. C. Bluck with 1 up. The "Henry Morris" challenge cup, awarded for the best score against Bogey under handicap, the winner also receiving the Medical Golfing Society gold medal, went to F. J. Smith for the second time with 4 up. The foursome sweepstake resulted in a tie between J. H. Drysdale and C. M. Hinds Howell and Clifford Price and J. H. Whitaker who returned scores of all square *v.* Bogey.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of this society was held at 6, Catherine-street, Strand, London, W.C., on June 19th. There were present: Dr. F. de Havilland Hall, in the chair; Mr. Frederick Wallace, Dr. St. Clair B. Shadwell, Dr. F. C. Martley (Dublin), Dr. H. A. Sansom, Dr. F. S. Palmer, Mr. J. Brindley James, Mr. W. Thomas (Birmingham), Dr. M. Greenwood, Dr. W. A. Dingle, Mr. F. S. Edwards, Dr. W. G. Dickinson, Dr. W. Knowsley Sibley, Dr. F. J. Allan, and Dr. J. B. Ball. Although the epidemic of influenza seems to have subsided the sickness claim lists of the society still show signs of its malevolence and the total disbursements under this head are somewhat beyond the expectation. On the other hand, the mortality experience of the society has been exceptionally good and there is every reason to hope that with the advent of warm summer weather the outgo of the society will as usual fall below the average and quickly make up for the heavy claim account of the winter and spring. The secretary is Mr. F. Addiscott, 33, Chancery-lane, London, W.C.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—An extraordinary general meeting of this society took place at its offices, No. 1, Upper Montague-street, Russell-square, London, W.C., on June 19th. The meeting was presided over by Dr. George Reid, medical officer of health to the Staffordshire county council and President of the society, who was heartily congratulated by the meeting on his return to his official duties after a long and serious illness. Resolutions were passed unanimously by which the membership of the society will be limited in future to two classes—viz., Fellows and Associates. It was also agreed that the Fellowship of the society shall be open to the following: Medical officers of health, acting or retired, whether in the British Isles and dependencies or elsewhere; medical officers (sanitary) of the navy and army (at home or abroad); all registered medical practitioners holding a Diploma in Sanitary Science, Public Health, or State Medicine, under Section 21 of the Medical Act, 1886; all medical inspectors of the Local Government Boards or other Government departments of England and Wales, Scotland, and Ireland; and medical officers appointed by education authorities. The confirmatory meeting will be held in the law courts at Cardiff on July 17th next.—The members of the Midland branch of the society met recently at the Foleshill Infectious Hospital, Coventry, by special invitation of the president, Dr. J. Orton. After inspecting the new hospital, which is regarded as a model one, the members held their business meeting and elected the following officers for the coming session:—President: Dr. R. Green (King's Norton). President-elect: Mr. F. H. May. Vice-Presidents: Professor A. Bostock Hill, Dr. J. H. H. Manley, Mr. H. May, and Dr. Orton. Council: Dr. T. Ridley Bailey, Dr. Sidney Barwise, Dr. G. Reid, Dr. P. Boobbyer, Dr. H. Malet, Dr. E. H. Snell, and Dr. J. Robertson. Honorary Treasurer: Professor Bostock Hill. Honorary Secretary: Dr. Snell. Representatives: Professor Bostock Hill and Dr. Manley. The most important item of business was the consideration of the extraordinary step taken by the Bilston urban district council in dismissing Dr. Ridley Bailey, medical officer of health of Bilston, from his position as medical superintendent of the fever hospital. Dr. Ridley Bailey is an ex-president of the South Staffordshire division of the British Medical Association and also an ex-president of the Incorporated Society of Medical Officers of Health. The fact that he has done excellent service as medical officer of health and as superintendent of the fever hospital at Bilston and that there have been no complaints as to the manner in which he has discharged his duties appears to have been admitted by those members of the council who supported this ill-advised motion, and the only reason brought forward in support of it was that the two appointments should not be held by one officer. The separation of these two offices is directly opposed to the best interests of public health and public convenience. The dismissal of a public officer in such circumstances and without clear reasons must have the effect of a vote of censure for which there is no possible justification, and from reports which are prevalent in the locality there appear to be urgent reasons in favour of an immediate public inquiry into the exact circumstances that have led up to the extraordinary step which was taken at the meeting. The following proposition was carried unanimously:—

> That this branch desires to express its indignation and astonishment at the extraordinary step taken by the urban district council of Bilston with regard to the appointment of their medical officer of health as superintendent of the fever hospital. The members of this branch feel that such a step casts a slur, not upon the medical officer of health, but upon the urban district of Bilston, and they feel confident that under the extraordinary circumstances of the case no medical man of any standing whatever in his profession would be found to accept the position thus made vacant.

PRIZE DISTRIBUTION AT ST. GEORGE'S HOSPITAL.—The prizes were presented to the successful students at St. George's Hospital on June 24th. The senior physician, Dr. H. D. Rolleston, having referred to the close connexion between the hospital and the school and to the interest which the governors had always taken in the medical education afforded at the hospital, called upon the Earl of Plymouth, who is one of the treasurers of the hospital, to distribute the prizes. Lord Plymouth, in congratulating the prize-winners, referred to the exceptional opportunities for gaining experience and tuition in their profession which are afforded to the medical students in the large hospitals of this country, and considered that such educational work was worthy of public support. The senior surgeon, Mr. C. T. Dent, proposed a vote of thanks to Lord Plymouth and expressed his misgivings as to the result if our hospitals ever came to look for their support to the rates. The vote having been duly seconded was passed unanimously.

THE ROYAL SANITARY INSTITUTE.—The twenty-fourth Congress of the Royal Sanitary Institute will be held at Cardiff from July 13th to 18th, under the Presidency of the Right Hon. the Earl of Plymouth. In the section devoted to sanitary science, which will be presided over by Dr. D. S. Davies, medical officer of health of Bristol, Dr. H. M. Richards, medical officer of health of Croydon, will introduce a discussion on Medical Inspection of School Children, and among the subjects to be dealt with at the eight special conferences held in connexion with the congress are Notification of Births, Regulations affecting the Transit and Sale of Food, and Meat and Milk in their Relation to Animal Tuberculosis. In connexion with the congress a health exhibition of apparatus and appliances relating to health and domestic use will be held as practical illustration of the application and carrying out of the principles and methods discussed at the meetings. Full particulars can be obtained from the Secretary, Royal Sanitary Institute, Margaret-street, London, W.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Milk Control (Scotland) Bill.

Mr. WATT has presented a Bill in the House of Commons "to amend and extend existing legislation relating to the milk-supplies of the rural and urban districts of Scotland." It was read a first time. The honourable Member has the support in this matter of Sir ANDREW TORRANCE, Mr. FINDLAY, Mr. MCCALLUM, Mr. BARNES, Mr. CHARLES PRICE, Mr. SUTHERLAND, and Mr. HALLEY STEWART.

Children and Alcohol.

An attempt was made by Mr. WEDGWOOD in the Standing Committee of the House of Commons on the Children's Bill on Tuesday, June 30th, to put a legislative check on the practice of giving gin and other intoxicating liquors to infants prevalent amongst certain sections of the poorer classes. The honourable Member moved the adoption of a new clause to carry out this purpose. It ran as follows: "If any person give, or cause to be given, to any child under the age of five any intoxicating liquor, or if the parent or guardian or the person having charge of such child permit such liquor to be given, except upon the order of a fully-qualified medical practitioner or for some urgent cause, he shall, on summary conviction, be liable to a fine not exceeding five pounds." The honourable Member found sympathy with the object he had in view and it was stated that there was a good deal of expert medical opinion behind the proposal. However, some members of the committee took the view that the proposal was going too far in advance of public opinion. The clause was ultimately rejected by 21 votes to 20.

Indecent Advertisements.

The Joint Committee of both Houses of Parliament which has been investigating the subject of lotteries and indecent advertisements has now concluded taking evidence. It is considering the terms of its report.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 24TH.

Escaped Lunatics.

Mr. REES asked the Secretary of State for the Home Department whether in view of the murders perpetrated, as was conjectured, by escaped lunatics who could not under the Lunacy Acts be retaken if they evaded recapture for 14 days, and in view of the condition of the law in this behalf under which a duly certified lunatic, dangerous to the community at large, became a free man if he could successfully secrete himself for a fortnight, he would consider the propriety of amending the statute concerned to the end that escaped lunatics might be lawfully recaptured and detained pending recertification.—Mr. GLADSTONE replied: The position is not quite that suggested in my honourable friend's question. It is true that 14 days is the limit of time within which a lunatic can be recaptured by the authorities or the servants of the institution from which he has escaped without a fresh order and certificate, but there is already full power under the provisions of Section 13 of the Lunacy Act, 1890, to deal with a lunatic not under proper care and control and other sections 15 and 16 of the same Act to deal with a lunatic wandering at large. Additional powers for dealing with urgent cases are given by Sections 20 and 21 of the same Act. In the opinion of the Lunacy Commissioners, with which I agree, there is no need for any amendment of the law such as is suggested by my honourable friend.

The Vaccination of Teachers.

Mr. RAMSAY MACDONALD asked the President of the Board of Education whether before issuing the new code he would reconsider the wording of the provision relating to the vaccination of teachers, with a view of making it clearer than it was that the Board of Education really meant that teachers having conscientious objections to being vaccinated should have their scruples respected by local education authorities.—Mr. RUNCIMAN replied: I have no power to require local education authorities to appoint or to refrain from rejecting any particular candidate, but certain alterations have been made in the Code with a view to removing the misconception which seems to have prevailed that the Board considers that the employment of unvaccinated teachers should be avoided.

THURSDAY, JUNE 25TH.

Prevention of Tuberculosis in Scotland.

Mr. GULLAND asked the Secretary for Scotland whether he was aware of the improved attitude of public opinion in Ireland on the subject of prevention of tuberculosis, due to the work of Lady Aberdeen; whether he was aware that public opinion in Scotland was maturing in favour of legislation; and whether he would introduce for Scotland a measure on the lines of the Tuberculosis Prevention (Ireland) Bill.—Mr. SINCLAIR replied: I am aware of the fact as stated and will keep the matter in view, but I may refer my honourable friend to the Local Government Board's circular of March 19th, 1906, and to the Public Health Amendment (Scotland) Act, 1907, from which it will be seen that every phase of pulmonary phthisis is already administratively provided for in Scotland by the existing public health legislation of that country. I may add that the Local Government Board are shortly to issue a second memorandum indicating the progress that has been made in the administrative control of the disease during the last two years, and the Board has already consented to the adoption of the Compulsory Notification Act by nine local authorities.

Condensed Skim Milk.

Answering Mr. FLYNN, Mr. MASTERMAN (Parliamentary Secretary to the Local Government Board) stated that he was not aware that there was a widespread system of scientific adulteration carried on in Holland and Belgium as regarded condensed skim milk. The article itself was very cheap. Samples were taken at the ports of entry by the customs officers with a view to preventing condensed skim milk from being introduced without being properly labelled, and the Local Government Board had lately prepared regulations under the Public Health (Regulations as to Food) Act of last session, which had already been issued in draft, and provided for unsound food of all kinds being examined and dealt with at the port of entry.

MONDAY, JUNE 29TH.

Telephones and Disease.

Mr. LONSDALE asked the Postmaster-General whether his attention had been called to a report by Dr. Francis J. Allan, medical officer of Westminster, with reference to the presence of disease germs in telephone mouth-pieces; and whether any steps were taken to disinfect telephones at public call offices under the control of the Post Office.—Mr. BUXTON replied: My attention has been called to the statement by Dr. Allan, which was not communicated to the Post Office but was published in THE LANCET. No trace of disease germs appears to have been found on five out of the six call-office telephones tested by Dr. Allan and the circumstances with regard to the sixth instrument, which is understood to be one in use at a railway station, appear to be quite exceptional. A special inquiry as regards the possible spread of infection by call-office telephones was made three years ago by the City medical officer of health, and a considerable number of call-office telephones were tested with the result that they were found to be free from disease germs. Steps are taken for regularly cleansing the telephones in public call-offices, and suggestions for an improved method of disinfection are under consideration. The whole matter is under careful consideration.

Mr. LONSDALE: Is the right honourable gentleman aware that certain eminent medical authorities are of opinion that in the absence of disinfection tuberculosis and diphtheria may be transmitted by the mouth-pieces?—Mr. BUXTON: They are disinfected. We are considering whether we cannot have a better method of disinfection. I shall be very glad to receive any communication from any medical officer who has views on the subject.

Milk Legislation.

Mr. EDWARD STRAUSS asked the President of the Local Government Board if he could inform the House whether his Milk Bill was yet framed, and when he would introduce it.—Mr. MASTERMAN (who answered on behalf of Mr. BURNS) said: The Bill is being prepared, but I cannot at present fix a date for its introduction.

The Portsmouth Dockyard Surgery.

Mr. T. F. RICHARDS asked the First Lord of the Admiralty how many cases of accident at the Portsmouth dockyard had been dealt with by the medical officers and by the surgery attendants respectively during the last six months; and what were the actual hours the medical officers were supposed to be in attendance at the dockyard surgery.—Mr. MCKENNA furnished the following written reply: During the past six months 5189 cases of accident have been treated at the dockyard surgery. The surgery attendants supply first-aid only. The medical officers are responsible for all treatment and there is therefore no separate list of cases treated by attendants. A medical officer is in actual attendance in the dockyard surgery from 9 A.M. till noon, and from 2 P.M. till 5 P.M. (bell-ringing). During the remainder of the 24 hours a medical officer is available at his official residence inside the dockyard.

TUESDAY, JUNE 30TH.

Medical Attendance for Postal Employees.

Mr. WILES asked the Postmaster-General whether, having regard to recent cases brought under his notice in which certificates of duly qualified medical practitioners, stating reason for sick absence of postal employees, had not been accepted by the department, he would state when he intended to put into operation the recommendations contained in the Hobhouse Committee's Report that free medical attendance should be provided for postal employees who resided in districts outside the four-mile radius.—Mr. BUXTON replied: I hope to bring into force the recommendation of the Select Committee respecting free medical attendance at home for persons living outside the visiting area of their medical officer on Oct. 1st next. It was not possible to bring this concession into force at the same time as the other concessions recommended by the committee on account of the complicated nature of the arrangements and the requisite notices to the medical men that were necessary for giving effect to it.

Telephones and Disease.

Sir EDWARD SASSOON asked the Postmaster-General whether he had read the report of Dr. Allan, the medical officer of health of the city of Westminster, relative to the liability of the users of telephones to contract tuberculosis; whether he was now convinced of the danger to public health to which his attention had already been drawn; and whether he would insist upon the adoption of the system of flat mouth-pieces, such as obtained in France with no disadvantage to the public service.—Mr. BUXTON answered: I have read the report of Dr. Allan, which was not communicated to the Post Office but was published in THE LANCET. Steps are taken for the regular cleansing of Post Office public telephones and suggestions for improved methods of disinfection are under consideration. Many appliances for attachment to telephones in order to prevent the danger of infection have been examined in connexion with the Post Office telephone system, but their use is open to many objections.—Washing with disinfectants is, in the opinion of medical experts, including Dr. Allan, the most effective safeguard.

The Statues on the British Medical Association Building.

Mr. SLOAN asked the Secretary of State for the Home Department whether his attention had been called to the character of some of the statues on the new building of the British Medical Association now in the course of erection in the Strand; and what action, if any, he intended to take in the matter.—Mr. GLADSTONE (by written answer) replied: I am not officially the arbiter either of taste or morals and I have no control over the decoration of private buildings unless they violate the law. Were it otherwise I should see no reason for interference.

Mr. HORNIMAN further asked the right honourable gentleman whether he proposed to call for a report from the Commissioner of Police on the statues, nude and otherwise, ornamenting or disfiguring the streets and open spaces, as well as public and other buildings in London, and as to their effect on public morals.—Mr. GLADSTONE answered: No, sir.

The Notification of Births Act.

Mr. ACLAND ALLEN asked the President of the Local Government Board whether his attention had been drawn to the fact that on April 9th a certified midwife was convicted under the Notification of Births Act for failing to notify the birth of a child, whilst no proceeding was taken against the father; and whether, in view of the fact that under the Act parents were responsible in the first instance for the notification of births, he would consider as to the advisability of issuing a circular to local authorities drawing their attention to the responsibility of parents in the matter.—Mr. MASTERMAN sent the following written reply in the name of Mr. BURNS: My attention has not been drawn to the particular case mentioned in the question. The Act, however, imposes the duty of notifying a birth alike on the father if he is actually residing in the house when the child is born, and on any person in attendance on the mother at the time of the birth or within six hours after it. It will be seen, therefore, that it is always the duty of the person in attendance to notify the birth although it is provided that a person shall not be liable to a penalty for failing to do so if he had reasonable grounds to believe that notice had been duly given by some other person. I issued a circular to the local authorities shortly after the passing of the Act in which I drew attention to the duties in this matter of the father and of the persons in attendance on the mother.

THE NEW IRISH UNIVERSITIES AND THE GENERAL MEDICAL COUNCIL.

The Standing Committee of the House of Commons which is charged with the consideration of the Irish Universities Bill on June 26th dealt with the clause which gives the new universities representation on the General Medical Council.

The clause as originally drafted ran as follows:—

"The governing body of each of the two new universities shall be entitled to choose one representative to be a Member of the General Council constituted by the Medical Acts; and section seven of the Medical Act, 1886, shall be read and have effect as if the two new universities were included therein in the place of the Royal University of Ireland."

Mr. BIRRELL moved as an amendment to insert the following provision in the clause: "Each of the two new universities is hereby empowered to hold qualifying examinations in medicine, surgery, and midwifery for the purpose of registration under the Medical Acts as if each of those universities had been a university in the United Kingdom legally qualified at the passing of the Medical Act, 1886, to grant diplomas in medicine and surgery, and the provisions of Part I. of that Act and any enactment amending the same shall be read and have effect accordingly."

The right honourable gentleman stated that the clause was to give a representative to each of the new universities on the General Medical Council. Representation had been given on the General Medical Council to the new universities in England such as the Universities of Liverpool and Leeds. Of course, it was right that the new universities should be empowered to hold qualifying examinations in medicine, surgery, and midwifery. It was necessary to give this power by express enactment and therefore he moved his amendment. The clause had been drawn on the same lines as clauses in the various Acts setting up new universities in England.

Mr. C. C. CRAIG thought that the Chief Secretary might have taken this opportunity of telling the committee what he meant to do with the Royal College of Surgeons in Ireland.

The CHAIRMAN (Mr. J. W. WILSON): Order, order. That cannot be discussed now.

Sir WILLIAM COLLINS said that the General Medical Council was already an unwieldy body, and now it was proposed that two members should be added to it to take the place of one. The Chief Secretary to the Lord Lieutenant was doubtless aware that the diploma of public health, or as it was sometimes called sanitary science, was now given by most of the bodies giving medical qualifications. He did not know whether the wording of the amendment which concerned medicine, surgery, and midwifery would include the granting of diplomas in public health. Certainly the new bodies in Ireland ought to be brought into line with others and he hoped that he would receive an assurance that they should not be precluded from granting these diplomas.

Mr. BIRRELL promised to look into the point with reference to diplomas in public health. He did not think it would be right that the new universities should be excluded from granting them.

The amendment proposed by Mr. BIRRELL was then inserted in the clause without a division.

On the question that the clause as amended should stand part of the Bill,

Mr. MOORE expressed the fear that the additional representation which the clause gave would disturb the balance of the General Medical Council. It seemed to him that by a side wind the committee was altering the constitution of that body without consulting it as to the right way to proceed. It seemed to him that the committee was asked to assume without inquiry that the medical qualifications of these two new universities were to be up to the standard of the General Medical Council. The Act of Parliament allowed the General Medical Council to make that inquiry for itself.

The clause was ultimately agreed to without a division.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

CAMERON, JOHN, M.D.Edin., D.Sc.St.And., has been appointed Lecturer on Anatomy in the Medical School of the Middlesex Hospital.

DOWLING, EDWARD ALFRED GRIFFITHS, L.R.C.P.Lond., M.R.C.S., L.D.S.Eng., has been appointed Honorary Dental Surgeon to the Bristol General Hospital.

GILBERT, WILLIAM, M.B., Ch.B.Glasg., has been appointed Senior House Surgeon at the Provincial Hospital, Port Elizabeth.

GRAHAM, CECIL I., F.R.C.S.Eng., has been appointed Assistant Surgeon for Diseases of the Ear, Nose, and Throat to St. Mary's Hospital.

HEATH, PHILIP MAYNARD, M.S.Lond., F.R.C.S.Eng., has been appointed Assistant Surgeon to the Metropolitan Hospital.

ILES, ARTHUR ERNEST, L.R.C.P., M.R.C.S., has been appointed House Surgeon at the Bristol General Hospital.

MAYNARD, E., F.R.C.S.Eng., has been appointed Senior House Surgeon at the Bristol General Hospital.

RUDGE, FREDERICK HENRY, L.R.C.P.Lond., M.R.C.S., has been appointed House Physician at the Bristol Royal Infirmary.

SHORT, L. J., M.B., B.S.Lond., has been appointed Assistant House Physician at the Bristol General Hospital.

TOMLINSON, P. S., L.R.C.P.Lond., M.R.C.S., has been appointed Casualty Officer at the Bristol General Hospital.

WALES, E. G., M.B.Cantab., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Downham Market District of the county of Norfolk.

WALLACE, A. F., M.B., Ch.B.Aberd., has been appointed House Surgeon to the Johannesburg Hospital.

WILLCOX, JOSEPH WILLIAM JAMES, M.B., B.S.Lond., L.R.C.P.Lond., M.R.C.S., has been appointed House Physician at the Bristol General Hospital.

WILSON, J., L.R.C.P.&S.Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Dumbarton District of the county of Dumbarton.

YOUNG, ROBERT ARTHUR, M.D., B.Sc.Lond., F.R.C.P., has been appointed Honorary General Physician to the City of London Lying-in Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

AYR COUNTY HOSPITAL.—Resident House Surgeon. Salary £70 per annum, with board and residence.

BERMONDSEY INFIRMARY, Lower-road, Rotherhithe, S.E.—First Assistant Medical Officer, unmarried. Salary £170 per annum, with rations, washing, apartments, and attendance.

BIRMINGHAM, UNIVERSITY OF.—Walter Myers Travelling Studentship. Value £150 for one year.

BRADFORD UNION HOSPITAL AND WORKHOUSE.—Assistant Resident Medical Officer. Salary £100 per annum, with rations, apartments, and washing.

BRENTWOOD, ESSEX COUNTY ASYLUM.—Fourth Assistant Medical Officer. Salary £150 per annum, with board, attendance, lodging, and washing.

BRIDGWATER HOSPITAL.—House Surgeon, for six months. Salary at rate of £80 per annum, with board, lodging, and washing.

BRITISH MEDICAL ASSOCIATION.—Assistant Medical Secretary. Salary £500 per annum.

BURY ST. EDMUNDS, WEST SUFFOLK GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, residence, and laundry.

CANCER HOSPITAL, Fulham-road, London, S.W.—Director of Cancer Research and Pathological Department. Salary £600 per annum. Also Assistant Anæsthetist. Salary 25 guineas per annum.

CARMARTHENSHIRE INFIRMARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, attendance, &c.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—Honorary Assistant Anæsthetist.

CHESTER, CITY OF.—Assistant Medical Officer of Health. Salary £250 per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £50 per annum, with board, residence, and washing.

CITY OF LONDON LYING-IN HOSPITAL, City-road, E.C.—Resident Medical Officer for four months, renewable. Salary at rate of £50 per annum, with board, lodging, and washing.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Physician. Salary £80 per annum, with board, residence, and washing.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Physician. Salary £25, with board, residence, laundry, &c.

EDINBURGH, UNIVERSITY OF.—Lectureship in Diseases of Tropical Climates. Salary £300 per annum.

ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—House Surgeon. Salary £72 per annum, with board, apartments, and washing.

FROME UNION.—Medical Officer. Salary £90 per annum and fees.

HAMPSTEAD GENERAL HOSPITAL.—Gynæcologists, Surgeon to the Throat and Ear Department, and Physician to the Skin Department.

HEREFORDSHIRE GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, and washing.

HERTFORD GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

HESTON AND ISLEWORTH URBAN DISTRICT COUNCIL.—Assistant Medical Officer of Health. Salary at rate of £200 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians for six months. Salary £25. Also Assistant Resident Medical Officer. Salary £100 per annum, with board and residence.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Surgeon to Out-patients. Also Anæsthetist.

IPSWICH, EAST SUFFOLK AND IPSWICH HOSPITAL.—House Surgeon. Salary £65.

LANCASTER, ROYAL LANCASTER INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, attendance, and washing.

LEEDS MATERNITY HOSPITAL.—Honorary Medical Officer.

LEEDS PUBLIC DISPENSARY.—Two Resident Medical Officers. Salary £100 per annum, with board and lodging. Also Two Honorary Assistant Dental Surgeons.

LIVERPOOL STANLEY HOSPITAL.—Junior House Surgeon. Salary £60 per annum, with board, residence, and washing.

LONDON HOSPITAL.—Clinical Pathologist. Salary £350 per annum.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon, non-resident, for six months. Salary at rate of £50 per annum. Also Anæsthetist.

MANCHESTER, UNIVERSITY OF.—Senior Demonstrator in Physiology. Salary £150, rising to £250 per annum.

MIDDLESEX HOSPITAL W.—Emden and Hollins Scholarships in the Cancer Research Laboratories, value £100 and £105 respectively.

MILE END OLD TOWN INFIRMARY AND WORKHOUSE, Bancroft-road, E.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

MONKWEARMOUTH AND SOUTHWICK HOSPITAL, Sunderland.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—Junior Resident Medical Officer. Salary £50 per annum, with board, lodging, &c.

NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Demonstrator of Bacteriology. Salary £250 per annum.

NORWICH, CITY OF.—Assistant Medical Officer of Health and Bacteriologist. Salary £130 per annum and allowances.

NOTTINGHAM CHILDREN'S HOSPITAL.—House Surgeon (female) for six months. Salary at rate of £80 per annum, with board, residence, and washing.

ORKNEY, PAPA WESTRAY PARISH COUNCIL.—Lady Medical Officer and Public Vaccinator. Salary £65 per annum, with fees, house, and garden.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Senior Obstetric Assistant (female). Salary £50, with board, lodging, and washing. Also Anæsthetist.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—House Physician for six months. Salary at rate of £60 per annum, with board, lodging, and washing.

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, London, E.C.—Honorary Assistant Surgeon.

ST. MARY'S HOSPITAL, London, W.—Assistant Anæsthetist, also Casualty House Surgeon, both for six months. Salary in each case £100 per annum, with board and residence.

SHEFFIELD ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £65 per annum, with board and residence. Also Assistant House Physician. Salary £60 per annum, with board and residence.

SHREWSBURY, SALOP INFIRMARY.—House Physician. Salary at rate of £80 per annum, with board and apartments.

TEIGNMOUTH HOSPITAL, S. Devon.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician for six months. Salary £30, with board, lodging, and laundry. Also Surgeon to Out-patients.

WARWICK, HATTON ASYLUM.—Third Assistant Medical Officer. Salary £135, with board, lodging, attendance, and laundry.

WEST HAM UNION INFIRMARY. Whipps Cross-road, Leytonstone, N.E.—Second Assistant Medical Officer. Salary £120 per annum, with allowances.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Assistant Surgeon. Also Surgical Registrar. Also Assistant Officer in Charge of the X-Ray Department.

WEST SUFFOLK COUNTY EDUCATION COMMITTEE.—Medical Inspector of School Children. Salary £250 per annum, with travelling expenses.

WEST SUSSEX AND CHICHESTER JOINT EDUCATION COMMITTEE.—Medical Inspector of Schools. Salary £350 per annum and expenses.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Honorary Physician. Also Junior House Surgeon. Salary at rate of £80 per annum, with board, residence, and washing.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

WHITCHURCH, NEAR CARDIFF, CITY MENTAL HOSPITAL.—Locum Tenens for two months. £4 4s. weekly and all found.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—Resident House Surgeon. Salary £120 per annum, with board and lodging.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the *Factory and Workshop* Act at King's Norton, in the county of Worcester; at Bexhill, in the county of Sussex; at Fleet, in the county of Hants; at Attleborough, in the county of Norfolk; and at Dreghorn, in the county of Ayr.

Births, Marriages, and Deaths.

BIRTHS.

CARROLL.—On June 26th, at Redlynch, Salisbury, the wife of Lieutenant-Colonel E. R. W. Carroll, I.M.S., of a son.

HALL.—On June 26th, at Compton-terrace, Highbury, N., the wife of C. Beauchamp Hall, F.R.C.S. Eng., of a daughter.

NUTTALL.—On June 25th, at Manchester-road, Bury, Lancashire, the wife of A. Peel Nuttall, M.D. Lond., of a daughter.

PEARSON.—On June 28th, at Manor-place, Edinburgh, the wife of Charles Mowbray Pearson, M.B., F.R.C.P.E., of a son.

RAIT.—On June 27th, at "Woodstock," Lyndhurst-gardens, Hampstead, the wife of Captain J. W. F. Rait, I.M.S., of a son.

MARRIAGES.

TICEHURST—TAYLOR.—On June 27th, at St. James's Church, Weybridge, Gerald Augustus Ticehurst, M.A., M.B. Cantab., to Henrietta Elizabeth, second daughter of William Bramley Taylor, J.P., M.R.C.S.

WRIGHT—SOWELS.—On June 29th, at St. Cuthbert's Church, Thetford, by the Rev. R. C. S. Sweeting, Vicar of St. Cuthbert's, assisted by the Rev. E. W. Hardy, Vicar of St. Mary's, Thetford, Thomas James Wright, F.R.C.S.E., of 50, Prince of Wales-road, Norwich, to Constance Margery, third daughter of William Edward Sowels, Esq., of "The Rookery," Thetford, Norfolk.

DEATHS.

COTTON.—On June 25th, of pneumonia, Holland John Cotton, M.D., aged 57 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE ALEXANDRA ORPHANAGE.

Sir Horace B. Marshall, chairman and treasurer of the Orphan Working School and Alexandra Orphanage, of which their Majesties the King and Queen are patrons and the Prince of Wales president, has sent us a pretty little illustrated book entitled "The Foster Mother," written by Miss Hulda Friederichs to commemorate the 150th year of the Orphan Working School at Maitland Park. The school was founded on May 10th, 1758, and is the oldest orphanage for both boys and girls in the country. Miss Friederichs describes in language full of tender feeling the work of the orphanage and gives brief details of the pathetic cases which receive the ministrations of the institution. The Orphan Working School gives a home to its dependents from babyhood, and perhaps no charity can be more deserving of support than one which cares for those children who stand helpless on the threshold of life, when it is of the utmost importance that their talents and instincts should be rightly directed. The institution is in need of funds, and sympathisers with its work should certainly obtain a copy of "The Foster Mother" either from the publishers, Messrs. Horace Marshall and Son, Temple-avenue, London, E.C., or from the offices of the orphanage, 73, Cheapside, E.C.

THE USE AND ABUSE OF DISTRICT NURSES.

To the Editor of THE LANCET.

SIR,—Your correspondent hardly makes out a case for the intervention of the General Medical Council for the purpose of limiting the sphere of action of district nurses. His letter is not altogether clear, but he seems to complain:—

1. That the nurse is "called in" in place of the medical man. She is called in in place of the "wise woman," and as she has had some training she is far more likely to advise rational treatment and the employment of a qualified man than is the "wise woman," who feels no responsibility and does not know enough to appreciate her own ignorance.
2. That she attends midwifery. The Midwives Act has established the position of the midwife, and the district midwife is under better control and does no more than other midwives.
3. That she acts as assistant sometimes to the club medical officer. The objection to the unqualified assistant was that he pretended to be a qualified man. No one supposes that the district nurse is a qualified medical man. If she takes some of the work off the poor underpaid club officer I fail to see any objection. In all kinds of practice a nurse is a great and legitimate help to a medical practitioner.
4. That she is underpaid. No doubt she is, but I don't think the General Medical Council can, or will, interfere!
5. That district visitors collect for the nurse on the understanding that she will save medical fees. If they do, they receive money under false pretences! It is the "wise woman" and not the trained nurse who boldly treats serious diseases. The common complaint against district nurses is that they are too ready to send for the medical man.

"Senex" does not, I am glad to see, question the use of the district nurse. The good that she does in bringing neglected children under skilled and rational treatment is immense, while her attention to the heads of school children alone justifies her existence.

I am, Sir, yours faithfully,

O. CLAYTON-JONES, M.B. Oxon.,
Hon. Sec. Silverton and Bickleigh Nursing Association.

June 29th, 1908.

TREATMENT BY CORRESPONDENCE.

THE following extract from a cheap newspaper has been forwarded to us:—

> THE DOCTOR AT HOME.
>
> To make the *Sunday Circle* a real home and family journal, we have arranged for a London M.D.—late of St. Bartholomew's Hospital, and M.B. of Cambridge University—to answer medical and health questions in this column. We know the vast interest that readers take in matters of health and hygiene, and we are sure this column will be much appreciated. All questions of general interest will be answered in this column free; but replies cannot appear in this column under three weeks. We have arranged, however, with our M.D. to send immediate replies, with prescriptions, if necessary, to readers who send a postal order for one shilling, and a stamped addressed envelope. Such cases will not be mentioned in this column. Address all inquiries to "Medical," *Sunday Circle* Office, 17, New Bridge-street, London, E.C.

The Cambridge Bachelor of Medicine who is also a London Doctor of Medicine is behaving unprofessionally. He is picking up shillings, under the anonymous position of the *Sunday Circle's* M.D., which he should know are not rightly earned, inasmuch as such treatment by correspondence can never be safe or effective.

oyal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. rmond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham)phthalmic, 2.30 P.M.), West London (2.30 P.M.).

RSDAY (9th).—St. Bartholomew's (1.30 P.M.), St. Thomas's 3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. eorge's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex 1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West ondon (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), letropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan 9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's 1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, 3t. the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the ral London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

: is most important that communications relating to the orial business of THE LANCET should be addressed *usively* "TO THE EDITOR," and not in any case to any tleman who may be supposed to be connected with the torial staff. It is urgently necessary that attention should given to this notice.

s especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

ectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

etters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

Ve cannot prescribe or recommend practitioners.

ocal papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

etters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1908, which was completed with the issue of June 27th, are given in this issue of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1908 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received:—*Hanley Sentinel, Wolverhampton Evening News, Bradford Observer, Brighton Argus, Daily Express, Cardiff Echo, Dublin Mail, Pall Mall Gazette, Leeds Evening Post, Glasgow Record, Glasgow Herald, Liverpool Daily Post, Blackburn Telegraph, The Spectator, Leeds and Yorkshire Mercury, Newcastle Daily Chronicle, Morning Leader, Glasgow Evening News, Bayswater Chronicle, Lloyd's Weekly News, Warrington Observer, North-Western Daily Mail, &c.*

Communications, Letters, &c., have been received from—

A.—Sir W. H. Allchin, Lond.; Mr. J. Elfick Adler, Lond.; Messrs Allen and Hanburys, Lond.; Mr. J. Astier, Asnières; Aberystwyth Infirmary, Secretary of; Argyll Motors, Lond.; Messrs. Abel and Imray, Lond.; Ardath Tobacco Co., Lond., Secretary of; A. T. S.; Messrs. C. Ash, Sons, and Co., Lond.; Anglo-American Pharmaceutical Co., Croydon; "Ars Vivendi" System Propaganda Committee, Lond., Secretary of; Mr. E. S. Atkinson, Liverpool.

B.—Mr. J. A. Barth, Liepzig; Mr. T. Bell, Lancaster; Messrs. Burroughs, Wellcome, and Co., Lond.; Brisbane Department of Agriculture, Secretary of; Mr. W. Bryce, Edinburgh; Barnsley Hall Asylum, Bromsgrove, Medical Superintendent of; Messrs. Baillière, Tindall, and Cox, Lond.; Mr. G. Burnside Buchanan, Glasgow; The Birmingham and District Trades and Property Association, Secretary of; Mr. R. W. Bruce, Lond.; Dr. F. G. Bushnell, Brighton; Messrs. Bloud and Co., Paris; British Medical Association, Lond., General Secretary of; *Birmingham Daily Post*, Proprietors of; Messrs. Blundell and Rigby, Lond.

C.—Mr. John F. Craig, Belfast; Messrs. Chancellor and Co., Lond.; Messrs. A. H. Cox and Co., Brighton; Société des Eaux de Contrexéville, l'Administrateur de la; Central London Throat and Ear Hospital, Dean of; Major-General Lord Cheylesmore, Lond.; Colonial Office, Lond.; *The Chemist and Druggist*, Lond., The Editor of; Dr. Hubert Chitty, Lond.; Cheltenham General Hospital, Secretary of; Messrs. Callard and Bowser, Lond.; Cardiff City Mental Hospital, Whitchurch, Clerk to the; Coal Smoke Abatement Society, Lond.; Coventry and Warwickshire Hospital, Coventry, Secretary of; *The Councils' Journal*, Lond.

D.—Dr. C. M. Douglas, Dunmow; Dr. J. Lawson Dick, Lond.; Derbyshire Royal Infirmary, Derby, Secretary of; Dold (Jacob) Packing Co., Buffalo, N.Y.; Dr. A. Duncan, Lond.; Messrs. A. Driver and Sons, Chelmsford.

E.—Mr. H. Elliot-Blake, Bognor; Mr. M. D. Eder, Lond.; East Suffolk and Ipswich Hospital, Ipswich, Secretary of; Messrs. Evans, Sons, Lescher, and Webb, Liverpool.

F.—The Fine Art Society, Lond.; Fermanagh County Hospital, Enniskillen, Secretary of; Farringdon Engineering Co., Lond.; Messrs. Flint and Durbridge, Lond.; Frome Union, Clerk to the; Messrs. Fairchild Bros. and Foster, Lond.; Messrs. Harvey Frost and Co., Lond.

G.—Mr. H. M. W. Gray, Aberdeen; Dr. Paul Guillon, Paris; Mr. A. Perceval Graves, jun., Lond.; Gt. Eastern Railway Co., Lond., Continental Traffic Manager of; Messrs. Glasier and Sons, Lond.; Grimsby and District Hospital, Secretary of; Mrs. Gihon, Harrogate; Gt. Northern Railway Co., Lond., Chief Passenger Agent of; Messrs. Greenberg and Co., Lond.; Messrs. R. W. Greeff and Co., Lond.; Guy's Hospital, Lond., Governors and Medical Staff of.

H.—Rev. C. F. Harford, Lond.; Dr. W. J. Howarth, Maidstone; Dr. W. E. Heilborn, Bradford; Professor H. J. Hutchens, Corbridge; Professor F. Hobday, Lond.; Mr. Jonathan Hutchinson, Lond.; Dr. Beatson Hird, Birmingham; Heston, &c., Urban District Council, Clerk to the; Messrs. F. A. Hardy and Co., Lond.; Herefordshire General Hospital, Hereford, Secretary of; Messrs. C. J. Hewlett and Son, Lond.; Mr. H. Hancock Lond.; Mr. Otto Holst, Eastbourne; Mr. Marcel Haas, Châlons-sur-Marne.

I.—Incorporated Society of Medical Officers of Health, Midland Branch, Handsworth, Hon. Secretary of; *Irish Times*, Dublin; Hon. Mrs. S. Ives, Halstead.

J.—Messrs. Jones Bros, Bristol.

K.—Messrs. J. Keele and Co., Lond.; Messrs. S. Kutnow and Co., Lond.: Professor Dr. A. Keller, Berlin; Dr. M. P. Kerrawalla, Lond.; Messrs. R. A. Knight and Co., Lond.; Mr. E. Knight, Lond.; Dr. E. Klein, Lond.

L.—Mr. H. K. Lewis, Lond.; Dr. R. J. Lytle, Southsea; Leeds Public Dispensary, Secretary of; Mr. W. W. Linney, Croydon; Livingstone College, Leyton, Principal of; Lynn Thomas and Skyrme Fund, Cardiff, Hon. Secretary of; Dr. H. A. Lediard, Carlisle; Dr. A. H. N. Lewers, Lond.; Mr. H. H. Lacy, Warwick; Mr. T. Laffan, Cashel.

M.—Mr. E. P. Minett, Lond., Messrs. Macmillan and Co., Lond.; Mr. C. Matthews, Lond.; Monkwearmouth, &c., Hospital, Sunderland, Secretary of; Dr. J. A. MacDougall, Bude; Medico-Psychological Association of Great Britain and Ireland, Lond., Hon. Secretary of; Mr. K. V. G. Menon, Malabar; Mr. W. Martindale, Lond.; Manchester Royal Infirmary, Secretary of.

N.—Dr. J. Niven, Manchester; Messrs. Newton and Co., Lond.; Mr. G. A. Nussbaum, Lond.: Norwich Corporation, Clerk to the; Nightingale Fund, Lond., Secretary of; North of England Obstetrical and Gynæcological Society, Hon. General Secretary of; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.

P.—Dr. C. Pascheff, Sofia; Messrs. Parkins and Gotto, Lond.; Messrs. Peacock and Hadley, Lond.

R.—Dr. J. W. Rob, Weybridge; Messrs. E. J. Reid and Co., Lond.; Mr. R. Redpath, Newcastle-on-Tyne; Rebman, Ltd., Lond.; Royal Society of Medicine, Lond., Secretary of; Registered Nurses' Society, Lond., Secretary of; Royal College of Surgeons of England, Lond., Conservator of Museum of; Royal Sanitary Institute, Lond., Secretary of; Mr. J. Mill Renton, Glasgow.

S.—Dr. J. Sellei, Budapest; St. Andrew's Hospital, Northampton, Clerk to the; Stepney Spare Motor Wheel Co., Llanelly; Dr. A. E. Stevens, Lond.; Dr. R. S. Srivastava, Almorah; Dr. J. Selkirk, Boston Spa; Star Engineering Co., Wolverhampton, Secretary of; *South Wales Argus*, Newport, Manager of; Mr. H. S. Stannus, Lond.; Messrs. Staples and Co., Lond.; Messrs. Sisley's Lond.; Major C. A. Stone, R.A.M.C., Luksan, Jalpaiguri; Mr. J. Smith, Lond.; Mr. T. J. Stafford, Dublin; St. George's Hospital Medical School, Lond., Dean of; The Sanitary Assurance Association, Lond.; "Student"; S. D. S.; Messrs. G. Street and Co., Lond.; Mr. G. C. Steinicke, Munich; *Sheffield Daily Telegraph*, Proprietors of; Messrs. W. H. Smith and Son, Manchester; Mr. A. Stiebler, Lond.

T.—Mr. J. Thin, Edinburgh; Training College for Teachers of the Deaf on the Pure Oral System, Lond., Director of; Taunton and Somerset Hospital, Secretary of; Mr. F. C. Turner Lond.; Dr. W. E. Taylor, Atlanta, U.S.A.

U.—University Tutorial Press, Cambridge, Schools Secretary of.

V.—Mr. H. Vaughan, Lond.; Messrs. J. W. Vickers and Co., Lond.

W.—Mr. W. A. Wharram, Leeds; Dr. J. R. Woodcock, Hereford; Sir W. Whitla, Belfast; West Bromwich District Hospital Secretary of; Western Valleys Medical Association, Newbridge (Mon.), Hon. Secretary of; Whitehaven, &c., Infirmary, Secretary of; West Sussex Education Committee, Horsham, Secretary of; Weston-super-Mare Hospital, Clerk to the; Dr. A. Marius Wilson, Cape Town; Mr. William Woodward, Liverpool.

Y.—Mr. W. H. Young, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. B. Anningson, Cambridge: Apollinaris Co., Lond., Secretary of; Mr. E. Arnold, Lond.; Lieut.-Col. A. Ambrose, A.M.S., Devizes; Messrs. Armour and Co., Lond., A. G. E.

B.—Dr. C. Ballabene, Stettin; Messrs. Boulton and Paul, Norwich; Messrs. Baker Bros., Lond.; Berkshire Education Committee, Reading, Secretary of: B. J. P., Lond.; Dr. A. Birmingham, Ballinrobe; Messrs. Brown and Pank, Lond; Dr. A. H. Brehaut, Guernsey; Mr. F. A. Brockhaus, Lond.; Mr. W. J. Best, Louth; Burntwood Asylum, Lichfield, Secretary of.

C.—Messrs. Carling and Co., Lond.; Messrs. E. Cook and Co., Lond.; Cunard SS. Co., Liverpool, Manager of; C. M.; C. C.: Messrs. Chandler, Ingram, and Bell, Toronto; C. G.; Messrs. J. W. Cooke and Co., Lond.; Carmarthenshire Infirmary, Carmarthen, Secretary of.

D.—Durham County Council Education Department, Cashier to the; Doctor, Boscombe; Dr. W. T. Dougal, Pittenweem; Mr. H. A. Dodd, Stockport; Messrs. Davy, Hill, and Hodgkinson, Lond.

E.—E. R.; E. P.; E. W. T.

F.—Messrs. Flynn and Co., Cork; Messrs. Findlater, Mackie, Todd, and Co., Lond.; Dr. J. Fawcett, Lond.; Mr. F. T. Fagge, Llanfairfechan; Dr. P. Ferreyrolles, La Bourboule.

G.—Dr. E. A. Gates, Florence; Mr. Green, Lond.

H.—Dr. E. R. Hunt, Brighton; Mr. P. E. Hoyland, Rotherham; Dr. R. S. Hindmarch, Gateshead; Colonel T. Howard, Hythe; Messrs. Hooper and Co., Lond.: Dr. P. Hatton, Paris; Hitchin Union, Clerk to the; Mr. T. H. Hewitt, Lond.; Dr. B. Holländer, Lond.; H. J. V.; H. S.; Dr. D. Hethcote, Barnard Castle.

J.—Mr. T. J. Jenkins, Henllan; J. A.; J. P. T.; J. A. B. T.; Jamkhandi, India, Chief Medical Officer of; Jetter and Scheerer Co., Lond., Secretary of; J. B. B.; Mr. Y. M. Jones-Humphreys, Cemmaes.

K.—King Edward VII. Sanatorium, Midhurst, Secretary of; Kathiawar, India, Agency Surgeon of; Dr. H. Cameron Kidd, Bromsgrove.

L.—Dr. S. O. Lawrence, Lond.; Lancashire County Asylum, Winwick, Clerk to the; London Association of Nurses, Superintendent of; Liverpool School of Tropical Medicine, Secretary of; Leicester Infirmary, Clerk to the; Leeds Maternity Hospital, Secretary of; Locum, Llandudno.

M.—Mr. J. D. Malcolm, Lond.; Dr. W. C. MacFetridge, Clonakilty: Maltine Manufacturing Co., Lond.; Mr. H. Morris, Lond.: Dr. C. R. P. Mitchell, Malvern; Mr. J. F. Mackenzie, Edinburgh; Messrs. C. Mitchell and Co., Lond.; Maldon Sanatorium, Medical Superintendent of; Mr. J. P. Milton, Yelverton; Manchester Medical Agency, Secretary of; Mr. D. Maguire, Templeboy; Mr. J. E. May, Lond.; Mr. G. F. The Croonian Lectures

ON

INBORN ERRORS OF METABOLISM.

Delivered before the Royal College of Physicians of London on June 18th, 23rd, 25th, and 30th, 1908,

By ARCHIBALD E. GARROD, M.A., M.D. Oxon., F.R.C.P. Lond.,

ASSISTANT PHYSICIAN TO, AND LECTURER ON CHEMICAL PATHOLOGY AT, ST. BARTHOLOMEW'S HOSPITAL; SENIOR PHYSICIAN, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

LECTURE II.[1]

Delivered on June 23rd.

ALKAPTONURIA.

MR. PRESIDENT AND FELLOWS,—Of inborn errors of metabolism, alkaptonuria is that of which we know most, and from the study of which most has been learnt. In itself it is a trifling matter, inconvenient rather than harmful, which only attracts attention because an infant stains its clothing, or because an adult fails to effect an insurance of his life. The medical man merely needs to be aware of its existence and to be acquainted with the methods for its recognition in order that he may not mistake it for troubles of graver kinds; but for the chemical physiologist and pathologist it is one of the most interesting of metabolic abnormalities. Not only has the study of alkaptonuria thrown much light upon the fate of the aromatic fractions of the proteins of the food and tissues but has also helped materially to reveal a fact of far wider significance—namely, that for each protein fraction, or group of allied fractions, a special catabolic path has been evolved.

When freshly passed the urine of an alkaptonuric seldom exhibits any abnormality of tint, but it quickly begins to darken in contact with the air. The darkening, which is associated with absorption of oxygen, commences at the free surface of the liquid and passes through various shades of brown to actual blackness. Alkalinity of reaction greatly hastens the change. Linen and woollen fabrics moistened with the urine become stained as by a photographic developer. On heating the urine with Fehling's solution a deep brown colour develops and copious reduction occurs, but the browning of the liquid in which the orange precipitate is suspended gives to the test a quite peculiar appearance, which should be recognised by anyone who has once seen it. An ammoniacal solution of silver nitrate is rapidly reduced, even in the cold. On heating the urine with Nylander's solution, a darkening is produced by the alkaline reagent, but no reduction of bismuth is brought about. With Millon's reagent a yellow precipitate is formed. The most striking reaction is observed when a dilute solution of ferric chloride is allowed to fall into the urine drop by drop. The fall of each drop is followed by the appearance of a deep blue colour, which lasts but for a moment, and the phenomenon is repeated until oxidation is completed. With yeast no fermentation occurs and the polarised ray is not rotated either to the right or left.

Our knowledge of alkaptonuria is dated from the year 1858, in which year Bödeker[2] detected, in the urine of a patient with glycosuria, a second reducing substance, not a sugar, to which, on account of its behaviour towards alkalies, he assigned the name of alkapton, a bilingual word derived from alkali and κάπτειν. However, indications of the anomaly may be detected in much earlier medical writings. Thus there can be no doubt that the case of an infant who passed black urine, described by Alexander Marcet[3] in 1823, was of this nature. It is true that Marcet knew nothing of the reducing properties of the urine, but he describes accurately its darkening in colour on standing, the staining of napkins, and the effect of the addition of an alkali; and mentions that the condition was present from the earliest days of the child's life. Until the early years of the nineteenth century no distinction was drawn in medical writings between urines which were black when passed and such as darkened on exposure to air, but it is difficult to suggest any other diagnosis than that of alkaptonuria for some cases referred to in works of the sixteenth and seventeenth centuries, such as that mentioned by G. A. Scribonius[4] (in 1584) of a schoolboy who, although he enjoyed good health, continuously excreted black urine, and that cited by Schenck[5] (in 1609) of a monk who exhibited a similar peculiarity and stated that he had done so all his life. The most interesting record of this kind is to be found in the work of Zacutus Lusitanus,[6] published in 1649. The patient was a boy who passed black urine and who, at the age of 14 years, was submitted to a drastic course of treatment which had for its aim the subduing of the fiery heat of his viscera, which was supposed to bring about the condition in question by charring and blackening his bile. Among the measures prescribed were bleedings, purgation, baths, a cold and watery diet, and drugs galore. None of these had any obvious effect, and eventually the patient, who tired of the futile and superfluous therapy, resolved to let things take their natural course. None of the predicted evils ensued, he married, begat a large family, and lived a long and healthy life, always passing urine black as ink.

That alkaptonuria is a very rare anomaly admits of no question, and many medical men of large experience have never met with it. Of its occurrence in several members of a family and of its mode of incidence I have already spoken at sufficient length in my first lecture. In the great majority of instances it is present from birth and persists throughout life, but has been said to have been developed as a temporary morbid sign in a very few exceptional cases. It gives rise to no symptoms save occasional dysuria with undue frequency of micturition, but some few alkaptonurics have developed in later life that peculiar tissue staining which Virchow[7] first described and to which he gave the name of ochronosis.

The essential feature of ochronosis is the staining of the cartilaginous structures of an inky blackness, but surface or sub-surface pigmentation is sometimes present and has rendered possible the recognition of the condition in living subjects. The tint of the blackened aural cartilages may show through the skin and give a slaty-blue colour to the hollows of the ears, black flecks may appear upon the conjunctivæ or even upon the skin of the face, and the knuckles may have a bluish tint. Less than 20 cases of ochronosis are on record, but it is becoming evident that rare as the condition is it yet has several distinct causes. Albrecht[8] first suggested that alkaptonuria was one of these, and Osler[9] described the development of surface pigmentation of the characteristic distribution and character in three elderly men who were well-authenticated alkaptonurics. Clemens[10] and A. Wagner[11] have recently supplied the conclusive demonstration of the presence of ochronotic pigmentation of the cartilages in the body of a man who was a subject of the urinary anomaly under discussion. In four of the recorded cases of ochronosis the pigmentation was apparently due to the application of carbolic acid to ulcers of the legs during long series of years.[12] In some of the remaining cases the urine has shown no peculiarity of tint, or if present it is not mentioned in the records, and in others dark urine was passed which does not seem to have been either of the alkaptonuric or carboluric variety.[13]

The evidence available leaves no doubt in the mind that alkaptonuria is one of the causes of ochronosis and that prolonged absorption of carbolic acid is another, but it would appear that not all alkaptonurics develop ochronosis in later life, and in the records of post-mortem examinations of alkaptonurics by Fürbringer[14] and Moraczewski[15] no mention is made of staining of the cartilages which, if present, could hardly have been overlooked. It is not yet possible to explain why in some cases oxidation and blackening should occur within the tissues during life.

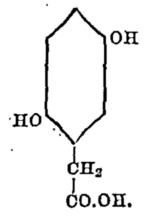
The substance which Bödeker isolated from the urine of his patient, and which he called alkapton, contained nitrogen and was obviously an impure material. In some cases afterwards recorded the abnormal constituent was thought to be pyrocatechin[16] and in others protocatechuic acid.[17] Marshall[18] obtained from the urine of his patient a substance which he named glycosuric acid, and R. Kirk,[19] investigating a group of cases in a single family, isolated an acid which he called uroleucic acid, which yielded on analysis percentages of carbon and hydrogen conforming closely to the requirements of the formula $C_9H_{10}O_5$. These two investigators, Marshall and Kirk, approached very nearly to the recognition of the actual nature and composition of the abnormal constituent. There are no sufficient grounds for supposing that the reducing substances present in these earlier cases were different from that found in all the more recent ones, and where re-examination of the urine or of material extracted therefrom has been possible the presence of homogentisic acid has since been demonstrated.

Homogentisic acid, the excretion of which is the essential feature of alkaptonuria, was isolated, analysed, and fully investigated by Wolkow and Baumann,[20] as is set forth in their classical paper, published in 1891, some five years later than the investigations of Marshall and Kirk. It was shown to have the empirical formula $C_8H_8O_4$; and the work of its discoverers, which has been confirmed by Huppert[21] and by syntheses effected in three different manners, by Baumann and Fränkel,[22] Osborne,[23] and Otto Neubauer and Flatow[24] respectively, has definitely proved that its constitution is that of paradioxybenzene-acetic acid (hydroquinone-acetic acid).



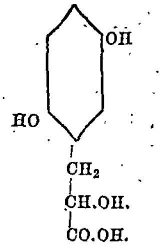
The acid was originally isolated from the urine as a lead salt, which may be obtained by an even far simpler method[25] than that employed by Wolkow and Baumann. The urine having been heated nearly to boiling, five grammes of solid neutral lead acetate are added for each 100 cubic centimetres of urine taken. A dense precipitate forms which is filtered off whilst the liquid is still hot, and the clear yellow filtrate is allowed to stand in a cool place. After a time lead homogentisate begins to separate out in crystalline form, and after 24 hours the crystals are filtered off, washed, and dried. The free acid may be obtained by passing sulphuretted hydrogen through ether in which the powdered lead salt is suspended. When the solvent, freed from lead sulphide by filtration, is allowed to evaporate colourless crystals of homogentisic acid are left and these melt at 146° to 147° C.

As alternative methods of extraction that of Wolkow and Baumann, in which the concentrated urine, acidified with sulphuric acid, is repeatedly extracted with ether, and the lead salt is thrown down from an aqueous solution of the residue from the ethereal extracts; or that of Erich Meyer,[26] which yields ethyl homogentisate, may be employed.

For the purpose of quantitative estimation of homogentisic acid in urine the volumetric method of Baumann[27] is made use of. This somewhat tedious method is based upon the reduction of a decinormal solution of silver nitrate in the presence of ammonia, but it is necessary to employ a stronger solution (8 per cent.) of ammonia than that prescribed by Baumann (3 per cent.) in order to obtain complete reduction in the allotted period of five minutes.[28]

Solutions of homogentisic acid yield all the characteristic reactions of alkapton urines: darken on exposure to air and more quickly when an alkali is added, reduce Fehling's solution on boiling and ammoniacal silver nitrate in the cold, and yield a transient blue colour with ferric chloride. Abderhalden and Falta[29] were able to detect the presence of the acid in the blood of an alkaptonuric man and to obtain the lead salt from the serum. From the fæces it is certainly absent, and I have failed to find it in the sweat. Ewald Stier[30] and Bandel[31] describe an unusual blackness of the aural wax of their patients, and from it the former obtained a substance which yielded the alkapton reactions.

In all the accounts of alkaptonuria written in recent years the statement will be found that in some cases there has been present in the urine, in addition to homogentisic acid, a second acid possessed of similar properties—viz., uroleucic acid, and that this substance is probably hydroquinone α-lactic acid.



This statement I believe to be grounded upon a misapprehension and to be incorrect, and the grounds for this belief have been fully set out in a recent paper written in conjunction with Dr. Hurtley.[32]

It will be remembered that the name of uroleucic acid was assigned by Kirk to the material which he isolated from the urine of his patients at a time before homogentisic acid was known. The late Dr. Kirk never claimed that this was a second distinct alkapton acid, and, indeed, in a letter to me he expressed his opinion that his uroleucic acid was merely impure homogentisic acid. Kirk's substance, to which as the result of his analyses he assigned the formula $C_9H_{10}O_5$, melted at about 133·3° C., whereas, as has already been mentioned, the melting point of homogentisic acid is 146° to 147° C. The analytical figures agreed very closely with the requirements of the above formula, and titration of a solution with alkali under a layer of petroleum ether gave a result which indicated a molecular weight corresponding to that of a monobasic acid of the above constitution. However, there is no room for doubt that Kirk's later surmise was correct and that in spite of these coincidences the substance which he analysed was impure homogentisic acid. Thus we found that when Kirk's method of extraction was applied to an alkapton urine in which a second acid had been sought for without success the product obtained agreed with his description of the lead salt which he obtained, and the free acid isolated from the lead salt melted at 134° to 136° C., but examination showed that it consisted mainly of homogentisic acid. It is known that the urines which Kirk examined contained this acid. Huppert obtained it from some of Kirk's original material, and we also found it in a further specimen of that material, blackened with age, but labelled "uroleucic acid." Moreover, when in 1902 I was enabled, by the kindness of Dr. Kirk, to examine fresh specimens of the urine of his patients much homogentisic acid was obtained from them but there was no indication of the presence of a second alkapton acid.

The view that the uroleucic acid of Kirk was a distinct substance had its origin in some investigations of the late Professor Huppert,[33] carried out upon some of the original material sent to him in 1897. After separation of as much as possible of the homogentisic acid which it contained a residue remained which melted at 130·5° C., and this residue Huppert regarded as uroleucic acid. Further investigations led him to the conclusion that it was a derivative of hydroquinone and was probably hydroquinone-α-lactic acid, which acid has the formula $C_9H_{10}O_5$ assigned by Kirk to uroleucic acid.

The accuracy of Professor Huppert's results does not admit of question, but it is evident that the scanty material at his disposal did not allow of a fresh analysis of the fraction of lower melting point, and if, as I believe, after careful comparison of Kirk's account of his investigations with Huppert's description of the material sent to him, and after personal examination of a further portion of the material, the substance examined was not a crude one, as Huppert supposed, but the actual uroleucic acid analysed by Kirk, it is obvious that the results of analyses of the material as a whole could not be applied to the fraction of lower melting point. Otto Neubauer and Flatow,[34] who have succeeded in effecting the synthesis of hydroquinone α-lactic acid, have shown that it differs from the supposed uroleucic acid in melting point and in other respects; and it is a significant fact that with the exception of a minute residue, which melted at 133° C., but which only sufficed for the determination of the melting point, obtained by Langstein and E. Meyer[35] from the urine of their patient, no indication of the presence of uroleucic acid has been found in any of the alkapton urines since described. Therefore the conclusion appears to be justified that no sufficient evidence is forthcoming of the occurrence in some alkapton urines of a second abnormal acid (uroleuic acid), a conclusion which has the advantage of making for simplicity. Beyond the presence in it of homogentisic acid the urine of alkaptonurics shows no obvious deviation from the normal. Some earlier investigators described a conspicuous diminution of the uric acid output, but more recent work has failed to confirm this. In a number of cases the excretion of uric acid has been found not to be below the average, and crystals of uric acid stained by the brown pigment are not infrequently deposited from such urines. We may therefore confine our attention to the consideration of the parent substances and mode of origin of homogentisic acid in the human organism.

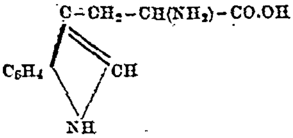
Seeing that there is no evidence that synthesis of the benzene ring ever occurs in the animal economy Wolkow and Baumann looked to the proteins of the food and tissues as the most likely sources of the alkapton acid and to the aromatic fractions which proteins contain—viz., tyrosin and phenyl-alanin—as its special precursors. This conjecture was shown to be correct by the result of the administration of *tyrosin* by the mouth to their alkaptonuric subject. Such administration caused a very conspicuous increase of the output of homogentisic acid. Since then this observation has frequently been repeated by other investigators, and the result has been shown to hold good for alkaptonurics in general. A corresponding increase follows an augmented intake of protein food and especially of such proteins as are unusually rich in the aromatic fractions.

Wolkow and Baumann were not able to test the effect of the administration of the phenyl-alanin, but at a later period Langstein and Meyer[36] arrived at the conclusion that the tyrosin of the proteins broken down in the metabolism of their alkaptonuric did not suffice to account for the quantity of alkapton acid which he excreted. This conclusion was based upon a comparison of the estimated daily output of homogentisic acid with that of nitrogen, which latter affords a measure of the protein destruction going on in the body. It was therefore probable that phenyl-alanin must also serve as a parent substance, and that it does so was afterwards demonstrated by Falta and Langstein[37] who found that phenyl-alanin given by the mouth increases the homogentisic output just as tyrosin does.

Falta[38] afterwards showed by a long series of feeding experiments with different proteins added to a constant diet, that the excretion of alkapton acid varies directly with the richness of the proteins given in phenyl-alanin and tyrosin, and arrived at the conclusion that on any given diet the output corresponds closely with that to be expected if the aromatic fractions of the catabolised proteins are wholly converted into homogentisic acid and excreted as such.

The yield of alkapton acid after feeding with tyrosin or phenyl-alanin varies with the mode of administration, and when small doses are given at short intervals, instead of a single large dose, the output is practically quantitative. This observation we owe to Mittelbach.[39]

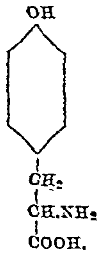
Yet one other of the known protein fractions has a benzene ring in its molecule, but in tryptophane the ring forms part of the more complex, heterocyclic, indol grouping. It appears unlikely *a priori* that the catabolism of tryptophane will follow the same path as tyrosin, and that it will become converted into homogentisic acid, but in order to test the point I recently administered one gramme of tryptophane, for which I was indebted to the kindness of Dr. F. G. Hopkins, to an alkaptonuric boy.



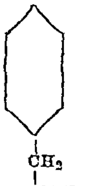
Tryptophane.

The dose was a small one, and any effect might be expected to be slight. Therefore an equivalent dose of tyrosin (0·9 gramme) was given on two occasions as a control, the patient being kept upon a constant diet. The effect of each dose of tyrosin upon the $\frac{\text{homogentisic acid}}{\text{nitrogen}}$ ratio was clearly marked, but no disturbance of the ratio was observed on the day on which the tryptophane was given. Hence I feel justified in concluding that tryptophane administered by the mouth does not increase the output of homogentisic acid. However, it would be desirable that this should be confirmed by the giving of larger doses. I may add that Dr. Hopkins, who was good enough to examine the urine of the tryptophane day, failed to find in it any abnormal constituent the presence of which could be ascribed to an error of tryptophane catabolism. To sum up, it would appear that the tyrosin and phenyl-alanin of proteins are the only parent substances of the alkapton acid.

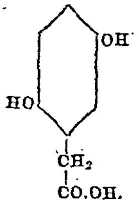
A glance at the respective formulæ of tyrosin and homogentisic acid suffices to show that the change from the one to the other is a complex one, for it involves the removal of the hydroxyl group from the para-position and substitution of two others in the 2:5 position in relation to the side chain, or possibly a shifting of the side chain itself.



Tyrosin.



Phenyl-alanin.



Homogentisic acid.

Such a change presented greater chemical difficulties when Baumann wrote than it does now and could not be paralleled in animal metabolism. As, however, such successive reduction and oxidation were known to be brought about by bacterial action, Wolkow and Baumann suggested that it might have its seat in the intestine of alkaptonurics, being there brought about under the influence of a rare specific micro-organism. Nowadays this infective theory, which was at one time widely accepted, has been completely abandoned, for it has been abundantly disproved.

Intestinal disinfection has no influence upon the excretion of homogentisic acid by alkaptonurics, nor can any organism be grown from their fæces which is able to effect such a conversion of tyrosin. Moreover, it has been shown by Mittelbach,[40] and afterwards by Langstein and Meyer and by Falta,[41] that abstinence from protein food, and indeed from all food, does not arrest the excretion of the acid, although it naturally greatly reduces its amount. Hence we must conclude that not the food proteins alone but also those of the tissues contribute their quota to the total output of homogentisic acid, which would not be the case if the conversion were effected in the alimentary canal and the fact, which we owe to Abderhalden, Bloch, and Rona,[42] that the soluble dipeptide glycyl-l-tyrosin when injected subcutaneously into an alkaptonuric produces the same effect as tyrosin introduced into the alimentary canal affords equally conclusive evidence that the change is not merely due to the action of intestinal bacteria.

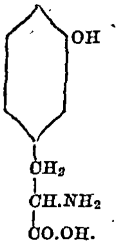
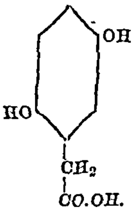
[39] Ibid., 1901, vol. lxxi., p. 50.

Lastly, if the aromatic fractions of the proteins were thus changed in the intestine before undergoing absorption therefrom, seeing that they are not synthesised in the animal organism, the tissue proteins of alkaptonurics should exhibit a shortage of tyrosin and phenyl-alanin, if, indeed, such a deviation from normality be compatible with the maintenance of life. Abderhalden and Falta,[43] who have investigated the blood proteins of such subjects as well as their hair and nails, have found no evidence of deficiency of the fractions in question.

The change from phenyl-alanin to homogentisic acid presents less difficulty than that from tyrosin, for that compound has no hydroxyl group upon the benzene ring, and it is not improbable that with tyrosin the removal of the parahydroxyl group and the oxidation in the 2 and 5 positions occur at quite distinct stages of the catabolic process, so that no shifting of the hydroxyl or of the side chain is involved. Such a view gains support from the fact, ascertained by L. Blum,[44] that metatyrosin, which he has prepared synthetically, and which has its hydroxyl group in the same position relatively to the side chain as one of the hydroxyls of homogentisic acid, is actually not converted into homogentisic acid when administered by the mouth, for it does not increase the output of that acid by an alkaptonuric. This behaviour of metatyrosin affords a further proof of a fact which had previously been demonstrated by Falta, namely, that substitutions upon the benzene ring are capable of preventing the formation of homogentisic acid from tyrosin. Falta[45] showed that a similar arrest occurs as the result of substitution of halogens, for neither dibrom-tyrosin nor the halogen proteins increase the homogentisic excretion of an alkaptonuric. On the other hand, as we shall see presently, the factor which determines such conversion is the structure of the side chain and the presence of a grouping which is readily attacked in connexion with the α carbon atom.



Metatyrosin.



Homogentisic acid.

It will be obvious, from all that has gone before, that the error of metabolism which is at the back of alkaptonuria is a failure to deal with the aromatic fractions of proteins in the ordinary way, and that both the proteins of the food and those of the tissues are implicated in the error. Before proceeding further it is, therefore, necessary to consider what is known as to the ordinary way of dealing with these fractions.

It is an unquestionable fact that the great majority of aromatic compounds, when introduced into the human organism, escape with their benzene ring intact and are excreted in the urine in combination with sulphuric acid, as aromatic sulphates, or with glycocoll, as the acids of the hippuric group. Not so tyrosin and phenyl-alanin, which are in no sense foreign substances but important constituents of proteins, for these suffer disintegration of the aromatic nucleus and are completely destroyed. It is true that they do not stand quite alone in this respect, nor is it to be expected that they should do so, for any aromatic substance which is an intermediate product of their catabolism will obviously be in like manner broken up, as also will compounds so closely allied to them in their molecular structure that when exposed to the same destructive influences they share their fate. Some recent investigations have supplied a clue to the seat of the destruction of such substances and the nature of the changes which they undergo. Thus, G. Embden, Saloman, and F. Schmidt[46] found that when certain protein substances are perfused through the liver acetone is formed. Glycocoll, alanin, glutaminic acid, and asparagin led to no such formation of acetone, but with leucin, tyrosin, and phenyl-alanin, as well as with phenyl α-lactic and homogentisic acids, a conspicuous yield of acetone was obtained. The aromatic acids on this list are all broken up in the normal organism, whereas phenyl β-lactic, phenyl-propionic, and phenyl-acetic acids, which are not so broken up, do not yield acetone in the perfused liver. Furthermore, J. Barr and L. Blum[47] have found that substances which figure in the above list of acetone-yielding compounds cause an increased excretion of β-oxybutyric acid when administered to diabetics. Hence they regard it as probable that the formation of acetone from them is a secondary event and that β-oxybutyric acid is first formed.

The question which next calls for consideration is whether in alkaptonuria the failure to deal with tyrosin and phenyl-alanin is or is not complete. In diabetes we are confronted with a failure to burn glucose, which may be of any degree, from such as leads to a small excretion of glucose only after a meal rich in carbohydrates, to a failure so nearly complete that the proteins are called upon to contribute to the urinary output of glucose. In congenital cases of alkaptonuria, at any rate, and concerning temporary cases no information on this point is forthcoming, the excretion of homogentisic acid, although it varies considerably, as it obviously must do, according to the nature of the diet taken, is fairly uniform in different cases, provided always that the food of the subjects is similar in kind and in proportions.[48] There is no evidence that the alkapton acid ever occurs in traces in the urine; an output of several grammes in the day is observed or no homogentisic acid is found. Four or five grammes a day is the average on an ordinary mixed diet. The evidence afforded by the ratio of homogentisic acid to nitrogen is of far greater value in this connexion than that derived from the measure of the daily output of homogentisic acid alone. A mere increased supply of a given protein in the food does not disturb this ratio, for with the increased destruction nitrogen and alkapton acid in the urine increase *pari passu*. But though unaffected by quantitative changes in the diet the ratio is profoundly disturbed by changes in the quality of the proteins taken, as must needs be the case, seeing that some proteins are far richer in tyrosin and phenyl-alanin than others, whereas their yield of nitrogen is comparatively constant. Thus the substitution of casein, which is rich in the aromatic fractions, for egg albumin, in which they are much more scantily present, will greatly increase the output of homogentisic acid relatively to that of nitrogen, as Langstein and Meyer and Falta have demonstrated.

If in alkaptonuria the error be complete and maximal, all subjects of that anomaly when fed upon a given standard diet should excrete equal quantities of homogentisic acid, and changes in the quantities consumed, although they will conspicuously affect the total output of the acid, should leave the H:N ratio $\left(\frac{\text{homogentisic acid}}{\text{nitrogen}}\right)$ undisturbed. In order to obtain conclusive evidence upon this point it would be necessary to place a number of alkaptonurics upon a standard diet, in which not only are the proteins the same but in which also the several proteins are represented in uniform proportions. These conditions would be best fulfilled by a diet of milk alone. Unfortunately, observations so carried out are not available, but such observations as are forthcoming strongly suggest that the error is in all cases of one degree, and that the failure to deal with tyrosin and phenyl-alanin is complete. The best available standard, although far from a uniform one, is a mixed diet, and the following figures are drawn from the observations of Langstein and Meyer and Falta upon one alkaptonuric, of Schumm upon another, and of Hele and myself upon yet three others. All the patients were, at the times to which the figures refer, upon a mixed diet, and the results serve to show that under roughly uniform conditions of diet the ratios show at least a striking similarity.[49]

[48] Most unusually high figures may be ascribed to the diet taken; but it should be mentioned that Zimper records figures for his case which are out of all proportion to those obtained in any other. The homogentisic acid output amounted to as much as 18 grammes per diem. The tyrosin and phenyl-alanin of proteins broken down could not account for such an excretion.

Note.—The above ratios are all some 5·8 per cent. too low, owing to the use of 3 per cent. ammonia in estimating homogentisic acid. The error so caused is fairly constant. The figures for Minnie L. are obtained by substracting 5·8 per cent. from each ratio, 8 per cent. ammonia having been used in this case. The first four columns relate to the same individual.

Some other observations bearing upon this point have been published in the last year or two. Cronvall[50] obtained ratios varying between 45:100 and 61:100 in his case, the mean being 55:100. As he used 8 per cent. ammonia in estimating the homogentisic acid the percentages of that acid must be reduced by 5·8 per cent. to render them comparable with those given in the table, and he himself suggested that the ratios were rendered higher by a considerable amount of milk in his patient's diet.

Gross and Allard[51] in a recent investigation obtained very high H:N ratios, 60-70:100, which they regarded as showing a want of uniformity in different cases, but their patient was taking large quantities of milk, on one day as much as three litres, and changes in the protein content of the diet appear to have been chiefly brought about by the addition or withdrawal of milk. Their ratios are comparable with those worked out by Langstein and E. Meyer during a period of milk and plasmon diet (average 62·6:100), and that the above explanation is correct is shown by the fact that even the addition of plasmon (sodium casein) to the diet scarcely affected the ratio, whereas when superposed upon an ordinary mixed diet it greatly increases the homogentisic output relatively to that of nitrogen. Abderhalden, Bloch, and Rona[52] also give some figures relating to yet another case, that of a boy, and the ratios obtained from these figures are somewhat low, the average for five days being 35·7:100. The nature of the diet is not mentioned.

So far as the available evidence goes it tends to show that there is only one degree of alkaptonuria, and that from a given quantity of a given protein all subjects of the anomaly tend to form and to excrete the same amount of homogentisic acid, and it is probable that that quantity is a maximal one, seeing that Falta has shown that the output of homogentisic acid corresponds roughly to the estimated amounts of the aromatic fractions in the proteins brok down.

Two explanations are possible of the fact that alkaptonurics excrete homogentisic acid whereas normal person do not. Either the alkapton acid is a strictly abnorma product formed by a perverted metabolism of tyrosin an phenyl-alanin, in virtue of which these protein fraction experience a wholly different fate from that which overtake them in the normal organism, or it is an intermediate product of normal metabolism which is usually completely destroyed and does not come to excretion, but which in alkaptonuria escapes destruction.

It may be premised that the behaviour of homogentisic acid in the organism is rather that of a normal product than that of an interloper. None of the chemical protective mechanisms are called into play to cope with it in alkaptonuria save that which is called out by any acid which is not destroyed in metabolism. It is excreted in simple combination with bases and not as an aromatic sulphate or in combination with glycocoll. Its next homologue, gentisic acid, on the other hand, although it is for the most part destroyed in passage through the body, is in part excreted as aromatic sulphate, as Likhatscheff[53] showed and as Neubauer and Falta[54] also found.

As an acid, homogentisic acid is in part combined with ammonia, for the protection against acid is in no wise selective. Erich Meyer[55] obtained evidence of an increased excretion of ammonia by an alkaptonuric child and Schumm[56] made a like observation in the case of an adult. In neither instance was the increase of urinary ammonia comparable with that observed in some pathological conditions, such as grave diabetes; for, as we have seen, the output of the acid itself is never large as compared with that of the acids of the acetone group in some morbid states.

It stands to reason that an intermediate product of catabolism which is normally absent from the excreta must needs be completely destroyed under ordinary conditions, and that homogentisic acid conforms to this requirement there is abundant evidence to show. Thus, although H. Embden[57] succeeded in producing a transitory alkaptonuria in himself by swallowing eight grammes of the acid, he found that smaller doses had no such effect. Falta,[58] too, failed to induce an excretion of the acid in himself and two others by taking quantities of from four to six grammes in repeated half-gramme doses at short intervals. Hence it is evident that homogentisic acid is a member of that small group of aromatic compounds the benzene ring of which is broken down in their passage through the body, and, as has been mentioned, further evidence of this is afforded by the fact that it yields acetone when perfused through the liver. In these respects it behaves as a normal intermediate product might be expected to do. That this destructive power may be overtaxed is shown by Embden's experiment upon himself and by those of Wolkow and Baumann upon dogs.[59] In normal persons such overtaxing can never occur, since the maximum daily output taken at a single dose will hardly give rise to experimental alkaptonuria; but in disease the power of destroying homogentisic acid is sometimes conspicuously lowered—for example, in grave cases of diabetes, as Langstein,[60] Falta,[61] and others have demonstrated.

[58] Loc. cit., sub. 38, p. 254.

Garnier and Voirin,[62] who were the first to suggest that homogentisic acid is a product of normal metabolism, were inclined to ascribe its presence in the urine to excessive production, the power of destroying it being overtaxed. Whether the power of destroying it were merely overtaxed or wholly lost it might be expected that homogentisic acid given by the mouth to an alkaptonuric will be excreted nearly quantitatively, being added to the ordinary output, and H. Embden showed that this is the case. If, however, it were merely a question of overtaxing, the output of the acid should be considerably less than the amount which corresponds to the whole of the aromatic fraction of the proteins broken down, but, as we have seen, there is reason to believe that the failure to deal with tyrosin and phenyl-alanin in the usual way is complete. On such grounds the more recent adherents of the intermediate product theory have held that the alkaptonuric differs from the normal individual in that he does not possess the power of destroying homogentisic acid.

This theory has lately been challenged by Grutterink and Hijmans van der Bergh,[63] and upon the following grounds. To patients who were found to have much impaired powers of destroying homogentisic acid taken by the mouth, being sufferers from diabetes or hepatic disease, and in one of whom as small a dose as two grammes caused a temporary alkaptonuria, these observers administered tyrosin in doses of 10 to 15 grammes. They argue that after such large doses of tyrosin sufficient homogentisic acid should have been formed to overtax the limited destructive power, supposing that it were a normal intermediate product, and that some should have been excreted in the patient's urine, whereas in no instance did such a result follow. This evidence cannot certainly be lightly set aside. However, we cannot be sure that at any moment sufficient alkapton acid would be in existence to overtax the destructive power, which although diminished was certainly not abolished. Nor is it certain that when such impairment results from disease the formation of homogentisic acid, as well as its destruction, is not interfered with. Grütterink and van der Bergh satisfied themselves that the tyrosin given was well absorbed, but they do not state whether tyrosin itself, or derivatives thereof, other than homogentisic acid, were sought for in the urine. Knoop[64] had previously raised a similar objection. He fed dogs with phenyl α-lactic acid, a compound which, like tyrosin, increases the homogentisic output of alkaptonurics. He, too, argued that, as the power of dogs to destroy homogentisic acid is known to be limited, if it were a normal product it should have appeared in the urine. However, the fact that some of the phenyl α-lactic acid was recovered as such from the urine suggests that a block occurred at an earlier stage in the catabolic series.

It appears to me that at present the evidence in favour of the theory of an intermediate product far outweighs that which can be brought against it. Perhaps the most serious objection which can be raised to the view that homogentisic acid is an abnormal product peculiar to alkaptonurics is that such a view involves the assumption that the alkaptonuric, who alone has the power of forming homogentisic acid, is also peculiar in having no power of destroying it when formed.

The impaired destruction of the alkapton acid which results from certain morbid conditions has also interesting bearings upon the question of temporary or intermittent alkaptonuria. The records of such cases are very few, only four or five in all, and further work upon such cases is much to be desired. In some of them the evidence that the condition was temporary is not conclusive and in others the evidence of the nature of the abnormal excretory product is not sufficiently complete for the establishment of so important a point. In none of them save in that of Zimnicki,[65] whose paper appeared in a Russian journal which I have not been able to obtain, have quantitative estimations been carried out. His patient, whose alkaptonuria was intermittent, suffered from hypertrophic cirrhosis of the liver. In Geyger's[66] case, also intermittent, the patient was a diabetic. Of strictly temporary cases that described by Carl Hirsch[67] is the most remarkable. A girl, aged 17 years, with a febrile gastro-enteric catarrh, passed for three days only a urine which darkened on standing, contained indican, and also yielded the alkapton reactions. From it Professor Siegfried extracted an acid which formed a sparingly soluble lead salt, but neither the melting point of the acid nor any analytical figures are given.

A temporary or intermittent excretion of homogentisic acid seems more compatible with the theory that it is a normal metabolic product than with the opposite theory. It is noteworthy that the diseases from which Geyger and Zimnicki's patients suffered were such as have been found to be sometimes attended by impaired destructive power of the acid in question, and is conceivable that in rare instances the impairment may proceed further and become practically complete. I realise, however, that what has been suggested above as to diminution of power of forming as well as of destroying the alkapton acid in such diseases may be equally urged against such an interpretation of the intermittent cases.

In support of the intermediate product theory certain observations of Gonnermann,[68] Bartels,[69] and others have been adduced as pointing to the formation of homogentisic acid in plants by the action of a tyrosinase upon tyrosin. The evidence brought forward has never appeared to me to be at all conclusive, and the investigations of Schultze,[70] who has failed to obtain any evidence of the formation of homogentisic acid under such conditions, have deprived this argument of all cogency.

Assuming it to be a fact that homogentisic acid is a product of normal metabolism, the results of the administration of various aromatic acids to alkaptonurics may reasonably be expected to throw light upon the higher intermediate steps between the parent protein fractions and that substance. Any compound which represents a link in the chain should, on the one hand, be destroyed, as tyrosin and homogentisic acid are in the normal organism, and on the other hand should increase the output of the latter by alkaptonurics. Any substance which does not behave in the manner indicated cannot form such an intermediate link.

Many aromatic acids have been administered to alkaptonurics at various times, but very few have been found to fulfil the above conditions. The most complete set of observations of the kind have been carried out by Otto Neubauer and Falta,[71] and their findings have recently been fully confirmed by Grutterink and van der Bergh.[72] It was found that compounds such as phenyl-acetic and phenyl-propionic acids, which have simple side chains, have no effect upon the output. Those which increase homogentisic excretion resemble tyrosin and phenyl-alanin in having an easily attacked grouping in the α position upon the side chain, whereas when the substituted group occupies the β position no such result follows. Thus phenyl α-lactic and phenyl-pyruvic acids are excreted as homogentisic acid, whereas phenyl β-lactic acid is not. Even the presence of a second substituted group in β position, as in phenyl-glyceric acid, suffices to prevent the transformation.

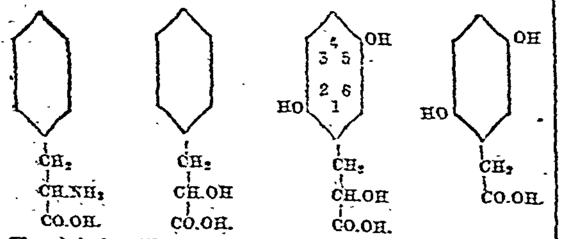
Phenyl-alanin. Phenyl-α-lactic acid. Phenyl-pyruvic acid. Phenyl-β-lactic acid. Phenyl-glyceric acid.

Again, when the substituted grouping in the α position is rendered more stable by benzoylation the formation of homogentisic acid is prevented, for, as L. Blum[73] has found, benzoyl-phenyl-alanin does not increase the alkapton output.

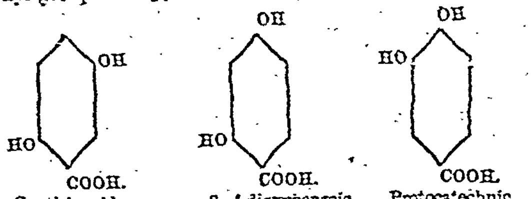
There is good reason to believe that desamination—that is to say, the removal of the amino group—is a very early stage in the catabolism of the amino-acids of which the molecules of proteins are built up, and of the aromatic fractions amongst others. After a meal rich in proteins the resulting excretion of homogentisic acid was found by Falta[74] to commence more promptly and to come to an end sooner than the corresponding increase of the output of nitrogen, and this has been confirmed by Langstein and Meyer. Mittelbach[75] placed the maximum excretion of homogentisic acid within the two or three hours following the protein meal, but in some observations which I made[76] upon specimens of urine passed at short intervals throughout the day, although an obvious increase occurred shortly after a meal rich in protein, the excretion was still larger during the second period of four hours than during the four hours immediately following the meal. It is highly probable that desamination is effected by substitution of hydroxyl for the amino group, and that the formation of α-lactic acid is the first step in the breaking down of phenyl-alanin. Not only does phenyl α-lactic acid fulfil the conditions laid down above, but it is one of the compounds which have been found to yield acetone when perfused through the liver.

Between phenyl α-lactic acid and homogentisic acid at least one other stage must intervene, for the introduction of the two hydroxyl groups in the 2 and 5 positions upon the benzene ring must precede the oxidation of the side chain. Were this not the case phenyl-acetic acid would be formed and the series of changes would be arrested, for phenyl-acetic acid has not the properties requisite for an intermediate product, being neither burnt by a normal individual nor converted into homogentisic acid by the alkaptonuric. The most likely intermediate product is hydroquinone α-lactic acid, which was formerly thought to be the uroleucic acid of Kirk.



Phenyl-alanin. Phenyl α-lactic acid. Hydroquinone α-lactic acid. Homogentisic acid.

With certain reserves as to substitutions upon the ring, the structure of the side chain clearly plays the chief part in determining the formation of homogentisic acid from tyrosin and phenyl-alanin, but apparently that which determines the disruption of the ring, and the destruction of homogentisic acid when it has been formed, is the presence of the two hydroxyl groups in the 2 and 5 positions upon the benzene ring. Thus, Neubauer and Falta found that of the three isomeric dioxybenzoic acids gentisic acid alone was to a large extent burnt in the human organism, although some 15 per cent. of the dose given appeared in the urine as aromatic sulphate. In gentisic acid, as in its homologue the alkapton acid, the hydroxyl groups occupy the 2 and 5 positions.



Gentisic acid. 2 : 4 dioxybenzoic acid. Protocatechuic acid.

When the alkaptonuric took gentisic acid by the mouth Neubauer and Falta found that the reducing power of his urine was conspicuously increased not owing to a greater output of homogentisic acid which could hardly have resulted but to the excretion of gentisic acid as such.

This indicates that in alkaptonuria the failure to break up the benzene ring extends to acids with hydroxyl groups in the 2 : 5 position other than homogentisic acid, and that the essential error resolves itself into an inability to destroy the ring of acids so constituted. Homogentisic acid is apparently the only compound formed in normal metabolism which offers itself for such disruption, and accordingly the alkaptonuric excretes it. It has been pointed out above that a higher intermediate compound of such structure must be formed, but this would appear to be changed to homogentisic acid before it comes into the grip of the destructive process.

This conception of the anomaly locates the error in the ante-penultimate stage of the catabolism of the aromatic protein fractions which is in accord with the fact that all the tyrosin and phenyl-alanin, both exogenous and endogenous, is swept into the net and goes to contribute to the excreted homogentisic acid in alkaptonuria.

We may further conceive that the splitting of the benzene ring in normal metabolism is the work of a special enzyme, that in congenital alkaptonuria this enzyme is wanting, whilst in disease its working may be partially or even completely inhibited.

The experiments of G. Embden and others upon perfusion of the liver suggest that organ as the most probable seat of the change. If, however, the acetone-forming enzyme is that which is at fault, it is worthy of note that not only the aromatic fractions of proteins but leucin also contributes to the formation of acetone and might be expected to be likewise involved. Dr. Hurtley was good enough to examine a large quantity of alkapton urine for me by extraction with ether after acidification, and distillation in steam of the residue of the ethereal extracts, but was unable to detect the presence of any abnormal acid of the fatty series, and there is at present no evidence forthcoming of any disturbance of the path of leucin catabolism in alkaptonuria.

THE NECESSITY FOR THE REMOVAL OF THE APPENDIX AFTER PERITYPHLITIC ABSCESS.

By WILLIAM HENRY BATTLE, F.R.C.S.,
SURGEON TO ST. THOMAS'S HOSPITAL.

IN a previous paper[1] I have considered the question as to the greater safety of the two methods of treatment of an appendix abscess, "simple incision with drainage of the abscess cavity," as compared with "incision, removal of the appendix, and drainage," and have given reasons for thinking the former much the better plan to follow, unless the abscess is small and the general condition of the patient satisfactory. In January, 1902,[2] a paper was published on the Advisability of Removing the Appendix Vermiformis after Suppuration caused by Appendicitis, and removal was strongly advocated, instances being given of recurrence of inflammation, localised suppuration, and even spreading peritonitis, some time after the primary abscess had closed and things quieted down. There could be little doubt even then that the statements of those who considered a localised suppuration "practically destroyed" the appendix were founded upon theory and not upon a practical knowledge of the subject, but it was not until experience had convinced surgeons generally that that opinion was wrong that such a decided feeling in the other direction set in, so that by many the rule now followed is to remove the appendix in every case at a convenient time if it was not done when the abscess was opened.

---

[1] Practitioner, 1907, p. 747.

[2] THE LANCET, Jan. 18th, 1902, p. 143.

In the discussion at the Royal Medical and Chirurgical Society on appendicitis[3] Sir F. Treves admitted that his opinion on this subject had changed. He said: "I was at one time disposed to think that the patient who had had a perityphlitic abscess was *ipso facto* cured of his malady, and that although he might have future trouble with the abscess he need fear no other attack of definite appendicitis. Longer experience has proved that this assumption is not correct." It is hardly necessary to recapitulate some of the reasons which possessed their value in the earlier stages of the discussion and which have been put forward elsewhere.[4] It is much more to the point to produce evidence which will carry weight with the unprejudiced observer of the present time, based on clinical and pathological grounds. As time passes one hears more and more instances related of renewed attacks of disease, some of which have terminated favourably, like the first, but others, unfortunately, in a fatal peritonitis. In fact, it may be at once stated that no patient is safe after an abscess of this kind until his appendix has been removed. No one can expect a patient with such extensive mischief as that invariably shown in the instances in which the pathological condition is described to escape further trouble. Such expectation would be against common sense. The outburst may not come immediately but it will come sooner or later.

It would be possible to bring forward many authenticated clinical accounts of cases in the practice of other surgeons in which recurrence of disease took place after abscess, but I am anxious to contribute independent evidence. In a series of cases brought before the Royal Medical and Chirurgical Society[5] there were several in which a return of symptoms was recorded. Amongst those now given, the number of these is proportionally much less because the appendix was removed whenever it was possible to obtain permission without waiting for symptoms.

The objections which have been put forward against removal in a quiet period after closure of the abscess are mainly two: (1) The operation is difficult and therefore dangerous; and (2) the cases in which it is required are few, because the appendix is obliterated by the process of destruction to which the suppuration and subsequent contraction have exposed it.

1. In answer to the first objection, it may be pointed out that not one of the cases in which this was done terminated fatally. In few did any suppuration follow in the wound, and these were mainly cases in which a sinus existed at the time of operation; there were no other complications. No surgeon would be deterred from performing an operation which might be difficult if he thought it necessary, and after all, the question of difficulty depends more on the individual experience of the surgeon than on anything else.

2. In reply to the second objection, it may be stated that this is incorrect, for the longer one lives the more instances affording proof to the contrary are met with. Before the discussion at the Royal Medical and Chirurgical Society the evidence as to the advisability of removal of the appendix in the class of case under discussion had been principally insisted upon by myself, and evidence chiefly depended on clinical facts. These, weighty and numerous, convinced many as increasing experience showed their true value. At that discussion I gave a description of the pathological condition of the appendix as met with, when removed in the circumstances now under consideration. In this paper further addition is made to that evidence. The condition of the appendix is not described in detail, as that would occupy too much space. Neither is any special attention drawn to complications which had resulted from the severity of the local inflammation. The pathological condition was found *to be as follows*:—

A. When the symptoms of appendicitis recurred or another abscess formed. Showing signs of recent inflammation, 1; chronic inflammation with scars of old perforation, 1; concretion and old perforation, 1; kinked, 1; kinked and adherent, 1; kinked, strictured, with scars of old perforations, 3; strictured, 2; strictured with retained concretions, 1; very adherent, strictured, old perforation, 1; universally thickened, stricture, scars of two perforations, concretions, 1.

B. Sinus formation after treatment of abscess. Chronic inflammation with close adhesions, 1; with old perforation, 1; recent perforation, 1; stricture, 1; stricture, concretion, old perforation, 1; very adherent, stricture, old perforation, 1.

C. Removal during a later peritonitis, the earlier abscess treated elsewhere. Recent perforation, 2; in one with a concretion.

D. Removal when no symptoms have arisen since the closure of the abscess. Marked chronic inflammation, 5; chronic inflammation with old perforation, 4; old perforation, 5; kinked, stricture, concretion, 1; kinked, stricture, perforation, 2; stricture, old perforation, 8; stricture, 9; doubled on itself, 1; contained thread worm, 1.

E. Removal after definite rupture into bowel. Marked chronic inflammation, 2; with old perforation at tip, 1; stricture, 1; kinked, stricture, recent perforation, 1; concretion, recent perforation, 1.

F. Removal during operation for evacuation of pus. Recent inflammation, 2, with recent perforation, 3, with concretion, 1. Chronic inflammation, 4. Stricture, 1; with recent perforation, 2. Gangrenous ulceration and perforation, 2.

G. Spontaneous rupture of abscess into peritoneum. Stricture, 2; gangrenous perforation with concretion, 2. In one fatal case, appendix long, curled on itself, acute inflammation with slough.

H. In some fatal cases in which the appendix had not been removed during life. Partial slough, 1; sloughed away with part of cæcum, 1; chronic inflammation, 1; concretion removed at operation.

In two cases the appendix was excised because of intermitting attacks of pain, not of inflammatory nature so far as could be ascertained. In one of these (a female, aged 65 years) an abscess had been opened seven years before and at the operation the appendix was atrophied but there were numerous adhesions of omentum to the right side of the pelvis, amongst which was a curiously shaped, oblong, ovarian dermoid, with a bony casing. In the second there was a strictured appendix and a concretion, associated with a suppurating ovarian cyst. It is evident, therefore, that the pathological condition of the appendix is quite as serious and as much a source of danger when it is apparently quiet and not yet producing symptoms as when it has already caused a recrudescence of inflammation. It is only necessary to compare the above lists together to appreciate this fact.

Statistics given as to the percentage of recurrence of trouble are of no value, as it is difficult to keep in touch with patients, some of whom would not return to the same surgeon or hospital if again ill. Also, a return of symptoms may take place any day during the life of the patient. Some have said that the finding of a concretion in the pus of an abscess is a sign that the cause of disease has been eliminated; this is wrong. In 20 cases fæcal concretions were found when the appendix was excised, in six cases concretions were found in the pus when the abscess was opened; in one it was the cause of a sinus which quickly healed after its removal. In one where a concretion was found in the pus the patient was readmitted later with renewed signs of inflammation and the appendix removed. In another a concretion was present in the pus of the abscess and another in the appendix when it was removed at a later date, whilst in two instances concretions were found outside the appendix when it was excised some time after the closure of the abscess. In many instances the second operation, that for the removal of the appendix, has fully justified itself by demonstrating the existence of a twisted, kinked, or strictured appendix. The finding of a concretion in the abscess is a proof of the nature of the abscess, if that is required, but it by no means follows that there is not another concretion in the appendix or that the perforation through which it has escaped will heal. There is always something besides the perforation, such as stricture or chronic inflammation.

---

[3] Transactions of the Royal Medical and Chirurgical Society, 1905 p. 445.

[4] Battle and Corner: The Surgical Diseases of the Appendix Vermiformis, &c., p. 96.

[5] Vol. lxxxviii., 1905.

The treatment employed in these cases, which include all that have a bearing on the condition of the appendix, was as follows. In 36 the appendix was afterwards removed at a time selected although there was no return of symptoms. In 24 there was a return or persistence of symptoms and the appendix was removed (appendicitis 8, abscess 6, sinus 6, peritonitis 2, iliac pain 2). In two the appendix was removed at the time of operation for spontaneous rupture of abscess into the peritoneum. In two it was removed at a second operation after this accident. In two other instances the patients did not recover after operation for this accident. In 14 the abscess was opened and the appendix removed at the time; one was in the sac of an inguinal hernia. Of these, two men died: one aged 57 years from cardiac seizure on the fifth day, and one aged 45 years from peritonitis on the second day. Even in cases when the appendix has come away as a slough there may be a stump left with a stricture in it and some mucous membrane beyond with power of secretion. This is as dangerous as an imperfectly removed appendix. The ages of the patients varied from three to 65 years. In no case in which secondary excision of the appendix was practised did any fatality occur. Localised suppuration in the wound occurred after operation for sinus on two occasions, and after secondary excision in clean cases, to a limited extent, three times. In one of them the remains of an abscess communicated with the cæcum at a spot where the peritoneum had been destroyed and it was necessary to arrange for drainage in case the suturing gave in the softened tissue; this it did, a fæcal sinus forming on the tenth day. In two the operation was performed through the scars of direct incisions made for the evacuation of pus by other surgeons; the abdominal wall was then (at the same operation) sutured in layers and a hernial protrusion cured.

The operation by displacement of the rectus after incision of the anterior part of its sheath, followed by section of the posterior part of the sheath, fulfils extremely well the requirements of these cases. It enables us to approach the seat of trouble at a point where there are few, if any, adhesions of the underlying structures; it permits of a thorough inspection of the area involved, which can be fully isolated before the appendix is touched, and the opening can be made as large as required without weakening the abdominal wall in later life. Its safety has been demonstrated in the above series of cases, and very many others; it never proved inadequate. This method of operation which I introduced to the profession several years ago is founded on the peculiarities of the anatomical arrangement of the muscles on the lateral aspect of the abdomen. It may be taken for practical purposes that the inner three-fifths of the distance between the anterior superior spine and the umbilicus is covered by the rectus muscle, that muscle extending much farther outwards than is generally recognised. The distance from the anterior superior spine to the outer margin of the rectus is really only about two inches; the total distance averages five and a half inches from the umbilicus to the anterior superior spine. To the outer side of the sheath, space is very limited unless muscular fibre is divided or torn. Incision of the sheath with displacement of the rectus gives a space which can be made of any desirable length without division of muscle, and leaves a solid living barrier across a line which would otherwise possess weakness. An incision is made through the skin and subcutaneous tissues down to the sheath of the rectus; this section is made obliquely downwards midway between the anterior superior spine and the umbilicus (and is not therefore over the line of the linea semilunaris, as stated erroneously by Messrs. Kelly and Hurdon, "The Vermiform Appendix and its Diseases," p. 534); is about four inches in length, varying with the deposit of fat in the abdominal wall of the individual, and is placed so that it is equally extended above and below the line. The outer margin of the rectus sheath can now be easily defined and during inspiration the direction of the pull of the aponeurosis of the external oblique muscle seen. The inner margin of the wound is retracted about half an inch and the anterior sheath of the rectus opened close to this retracted inner margin for the full extent of the incision. The rectus muscle is now drawn inwards, being separated from the outer part of the sheath with a few touches of the knife. Occasionally one of the lineæ transversæ requires to be separated from the sheath. An anatomical point of importance is the level of the transversalis fascia as regards the wound; the posterior layer of the sheath is strengthened and it makes the hold of the sutures much firmer if the opening into the peritoneal cavity can be confined to a part covered by this fascia; this opening is frequently less than an inch in length.

After amputation of the appendix by any method considered best, the posterior layer of the sheath and peritoneum are sutured as one layer by continuous or interrupted sutures, the rectus permitted to return to its bed, and the anterior layer of the sheath and superficial structures brought together and sutured in the usual manner. It has been called the "indirect" method, but it will be found when the appendix and cæcum are lifted up that the base of the appendix comes exactly into the middle of the wound. It permits, if necessary, of free exploration and manipulation of any structure from the gall-bladder to the floor of the pelvis. Even extremely long incisions have not been followed in my practice by any weakness of the abdominal wall. In simple cases it is not necessary to divide any nerve, and it should not be done, but I have not found such section to be followed by paralysis or wasting.

The after-course of operation by this method is singularly free from local suppuration and thrombosis or embolism of distant vessels, as veins are not bruised or torn nor are muscular tissues in any way lacerated or divided. Attention must be paid to the position of the deep epigastric vessels and their possible anomalies, otherwise they may cause trouble during the application of sutures to the posterior part of the sheath. The best time for removal of the appendix after localised suppuration is when the abscess has recently closed, for then adhesions in the neighbourhood are comparatively easy to deal with, and those which threaten danger in the future can be separated. In some instances of strong adhesions between contiguous coils it has been thought best to bring the peritoneum over the raw surface after separation in order to diminish the possibility of the formation of a fresh attachment. At this time, too, the bowel has recovered its tone and will hold sutures if their insertion is necessary. The usual stay in hospital after the operation is 14 days and no abdominal belt of any kind is required.

To sum up. The treatment of perityphlitic abscess is most safely carried out in two stages: first stage, evacuation of pus and drainage; second stage, removal of the appendix.

The necessity for removal of the appendix.—The statements of those who held that the appendix was obliterated by suppuration around it were erroneous; it is never obliterated but remains the subject of gross disease which in many instances (20 out of 70) gives rise to a return of symptoms within a short period after the closure of the abscess. The lesions found in those cases in which the appendix has been removed for a return of symptoms do not differ in their character from those found when it has been removed as a matter of routine without waiting for symptoms. Compared with a series of appendices removed for recurring attacks, without evidence of suppuration, the lesions found after removal following abscess are more gross and give fewer instances of apparent recovery from disease. Removal of the appendix after closure of the abscess is a safe procedure, and is not followed by any weakness of the abdominal wall if done in the way suggested. Moreover, operation at an early date after closure of the abscess enables the surgeon to treat dangerous adhesions and deal with any pelvic disease which may complicate the condition.

Harley-street, W.

ELEMENTARY SCHOOLS AND MEDICAL CHARITIES.—As the result of the annual collection organised by the Brighton and Hove Teachers' Association in the elementary schools of those towns a sum of £100 has just been tributed among the medical charities in Brighton Hove. This is the fourth year in which these coll have been made.

A CASE OF SARCOMATOSIS OF LYMPHATIC GLANDS.

By WALTER K. HUNTER, *M.D., D.Sc. Glasg.*,
PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY; LECTURER IN PRACTICE OF MEDICINE, QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW.

In reading over the literature dealing with diseases of lymphatic glands one cannot but be impressed with the difficulty which the authors seem to have in classifying the different morbid processes which fall to be included under this heading. No doubt this depends to a large extent on a lack of information as to the etiology of these conditions—as to whether they are simply different manifestations of the same disease, or whether each has its own specific virus producing it. But at the same time one recognises that where the specific cause is unknown the classification of disease must depend largely on a study of the symptoms and pathological anatomy that the different cases present to us. Hence it would seem of importance, if advance is to be made in our knowledge of this group of diseases, that the individual cases as they occur be carefully studied and recorded, both from the pathological as well as the clinical point of view. Disease of lymphatic glands, other than tuberculous disease, is, however, rather rare. A physician in busy practice sees few such cases in one year, and few physicians see any considerable number even in a life-time. This being so one scarce needs to offer an apology for having but one case as a contribution to the discussion.

A miner, aged 38 years, came under my care on Sept. 1st, 1906. His illness seemed to date from August, 1905, when for the first time he noticed a lump of about the size of a marble situated immediately below and behind the angle of the right jaw. In a fortnight's time this tumour had increased considerably and was then as large as a pigeon's egg. Iodine was applied over the swelling but with no apparent benefit, for it still increased in size, and other little tumours, as large as peas, could be felt in the tissues in the immediate neighbourhood. About the end of December, 1905, there was noted a swelling on the left side of the neck, similar in appearance to that on the right side, but it (the former) did not grow so rapidly as the latter. There seems to have been little constitutional disturbance and the patient was able to remain at his work, which was fairly laborious, till the end of January, 1906. Shortly after (in February) he was admitted into the Glasgow Royal Infirmary under the care of Dr. D. C. McVail. At this time there was noted to be considerable glandular enlargement on both sides of the neck but much more marked on the right. On that side there was a mass of glands extending from the mastoid process down to the clavicle and seeming to pass downwards behind that bone into the chest. The individual glands varied in size from that of a pea to that of a walnut. There was no apparent matting together and no signs of inflammation. The consistence of the glands varied, some being very dense and others more or less elastic. On the left side there was one gland situated behind and beneath the angle of the jaw as large as the largest on the right side, but the other glands on this side were not larger than peas and seemed rather deeply placed in the tissues of the neck. There was no evidence at this time of glandular enlargement elsewhere, either in the axilla, the groin, or the mediastinum, and neither liver nor spleen was enlarged. Examination of the blood showed no abnormality. The condition was diagnosed as Hodgkin's disease and the patient was treated with arsenic. While in the infirmary there was very marked improvement as regards the swelling in the neck, and when the patient was dismissed on March 23rd the tumour on the left side was scarcely noticeable, though on the right the glands were still definitely enlarged. On admission his shirt, he said, would not meet round his neck by two inches, while on dismissal it buttoned quite easily. The patient continued taking arsenic for the next two months and for the first fortnight of that time he remained very well. Subsequent to that, however, the glands again increased in size and he was readmitted to hospital in August, 1906. At this time the appearance of the neck was much the same as on admission to hospital six months previously, though the individual glands were not so moveable. There was now, however, a swelling in the roof of the mouth of the size of a gooseberry, situated at the junction of the soft and hard palate and lying slightly to the right of the middle line. It was not tender to the touch and did not affect swallowing; it had been noted since the middle of July. About this time the glands in the right axilla also began to enlarge but there was no glandular enlargement elsewhere to be made out otherwise than in the neck. Treatment with arsenic was resumed on August 4th and for the next four weeks the glands on the left side of the neck diminished considerably in size, though those on the right side seemed to remain stationary. There was little change in the tumour in the roof of the mouth.

At the beginning of September there appeared over the right pectoral region what seemed to be a subcutaneous œdema, but there were no dilated veins, and at that time no subcutaneous nodules were noted. There was, however, a slight increase in the manubrial dulness and the note in the left infraclavicular and lower interscapular regions was less resonant than at corresponding areas on the right side. The breath sound was rather feeble over both lungs. On Sept. 12th Roentgen-ray treatment was commenced, the rays being applied over the glands of the neck almost every day for a period of four weeks. As a result of this treatment there seemed an undoubted decrease in the size of the cervical tumours, but, on the other hand, the swelling in the right pectoral region seemed to increase more rapidly and ultimately small subcutaneous nodules could be made out, extending downwards as far as the right nipple. With the x ray treatment there was a great increase in the excretion of urea, as is shown by the following table:—

Average Amount of Urea excreted Daily.

For six days prior to treatment			... ...	= 350	grains.
For 1st six days after treatment commenced			...	= 450	"
" 2nd	"	"	" ...	= 518	"
" 3rd	"	"	" ...	= 741	"
" 4th	"	"	" ...	= 598	"
" 5th	"	"	" ...	= 707	"

The kind and amount of food given during the time these observations were carried out did not vary to any appreciable extent.

During the month of September the patient's general condition showed no improvement. Towards the end of the month the breathing became noisy, especially at night, and from time to time there was a certain amount of dyspnœa. The temperature, too, from about the middle of August onwards showed a distinct febrile reaction, the range of the evening temperature being from 99° to 102° F. By the beginning of October there were signs of pressure at the base of the brain in the form of a marked internal strabismus of the right eye. On Oct. 13th the patient sat up in bed and cried out that he was choking, a quantity of blood welled up from the mouth from time to time—several pints in all—the pulse failed, and shortly afterwards death supervened. The blood was examined while in hospital and the results are as follows. August 2nd, 1906: red corpuscles, 5,200,000 per cubic millimetre; white corpuscles, 6864 per cubic millimetre; and hæmoglobin, 65 per cent. Sept. 3rd: red corpuscles, 5,610,000 per cubic millimetre; white corpuscles, 7616 per cubic millimetre; and hæmoglobin, 70 per cent. Time of coagulability, seven and a half minutes. Films were examined on Sept. 7th but showed little abnormality, the red cells being normal in size and shape. Of the white cells 81 per cent. were polynuclears, 18 per cent. mononuclears, and 1 per cent. eosinophiles. The vast majority of the mononuclears were medium-sized hyaline cells, the proportion of the typical small lymphocytes being very small. The white cells were counted again on Sept. 22nd and numbered 7984 per cubic millimetre.

At the post-mortem examination, which was made by Dr. Mary B. Hannay, the whole of the neck was seen to be greatly swollen, especially on the right side. This swelling on further investigation was found to be due to a large white mass of new growth surrounding the larynx, trachea, and œsophagus. The tonsils could not be seen on account of the growth involving the soft palate and pharynx. The tongue, larynx, trachea, œsophagus, and thyroid gland all seemed normal, but lying along the trachea there were numerous enlarged isolated glands. Near the root of the lung there was a calcareous gland and one that was caseous. The lungs were emphysematous and the upper right lobe was in a.

state of grey hepatisation. The heart was flabby and its right ventricle somewhat dilated. The valve segments were normal, except for a single warty vegetation on one of the aortic cusps. On the right side of the chest extending down to the nipple there were a large number of subcutaneous nodules of about the size of slightly enlarged lymphatic glands. This same nodular condition was present on the left side of the neck. The chest wall (skin and subcutaneous tissue), especially in the region of the manubrium sterni, was greatly thickened, being about an inch in thickness, and the subcutaneous tissue was infiltrated with new growth continuous with that on the front of the neck. On examining the brain there was seen to be distinct flattening of the pons and medulla on the right side. The pituitary body was considerably enlarged. There was great swelling of the right basilar region and dorsum sellæ. The bones in these areas were soft and when cut with a knife new growth and pus exuded. There was an enlarged mass of glands in each axilla, and the glands of the groin were also slightly enlarged. The peritoneum and omentum were normal but the mesenteric glands were distinctly enlarged. The intestines seemed normal; Peyer's patches were not enlarged. The liver was large (73 ounces) and slightly fatty. The spleen was also enlarged (11 ounces) but otherwise normal. The kidneys and adrenals were normal. The marrow in the shaft of the femur was red.

On microscopic examination the tumour mass was found to be a large round-celled sarcoma; the same structure was found in tissue taken from the neck, from the roof of the mouth, the pituitary body, from the muscle of the anterior chest wall, and from a bronchial gland. In a mesenteric gland examined there was a certain amount of fibrosis but the appearances otherwise were normal. Peyer's patches were likewise normal. The axillary glands were not examined. The spleen, pancreas, and suprarenals were normal. The kidneys showed some slight parenchymatous nephritis. The marrow from the shaft of the femur had the structure of an ordinary active marrow but there was no sign of tumour growth. The marrow from one of the ribs was normal.

This case, then, would seem to have a clinical as well as a pathological interest. For the first 12 months after the appearance of the swelling in the neck the symptoms were entirely those of Hodgkin's disease, though one recognises that the glandular enlargement was less widespread and more definitely confined to the cervical region than is commonly met with in that condition. Still, there was nothing during these months to suggest that the growth was extending through the capsules of the glands to the tissues round about. The great improvement, too, on administration of arsenic is such as one sees in Hodgkin's disease. It may be insisted that examination of the blood showed no relative lymphocytosis, which is said by Pinkus[1] to be characteristic of pseudo-leukæmia. But, on the other hand, a study[2] of the blood counts in several series of cases makes it extremely doubtful if such a lymphocytosis does exist in this disease, or, indeed, if there is any constant and characteristic change in the blood. However, with the appearance of the swelling in the roof of the mouth, and especially with the infiltration of the pectoral region, it was apparent that the diagnosis had to be reconsidered. But it did not seem impossible that the case had originally been one of Hodgkin's disease which later had become sarcomatous. Pinkus[3] says it is not rare to find a lymphosarcoma grafted on to an already existing lymphomatosis (pseudo-leukæmia, Hodgkin's disease). Here, however, it must be pointed out that there is some confusion regarding the use of these names, for there are apparently two distinct pathological conditions included under the term pseudo-leukæmia or Hodgkin's disease. In the one (leukæmic type) the histological structure of the enlarged gland is exactly the same as in lymphatic leukæmia—i.e., there is a "hyperplasia" of the lymphoid elements of the gland. Such cases might therefore be best regarded as cases of lymphatic leukæmia without increase of lymphocytes in the blood. In the other type (fibrous type) the change affects the reticulum of the gland, and as the gland becomes more and more fibrous, the lymphoid elements become less conspicuous, and may ultimately almost entirely disappear. The process is, therefore, not a hyperplasia of the lymphoid elements as in the first type, but an atrophy of these, with a hyperplasia of what are probably stroma cells (large cells with irregular ragged cell-body composed of indefinitely granular protoplasm and with a large sharply outlined vesicular nucleus, sometimes round but more often kidney shaped).[4] Pinkus would only include the former of these two types under the term pseudo-leukæmia, while the latter he regards as an entirely different condition, as being, indeed, a special form of tuberculosis of lymphatic glands. And when he speaks of lymphosarcoma being grafted on to pseudo-leukæmia he refers to the leukæmic type of that disease.

That the glands in lymphatic leukæmia (or pseudo-leukæmia) should take on a lymphosarcomatous character is readily understood, for the structure of the lymphosarcoma is very similar to that of the glands in lymphatic leukæmia, and it may be a matter of difficulty to distinguish the one from the other histologically. In the former the growth tends to go through the capsule of the gland and invade adjacent tissue, while in the latter such is supposed not to occur, though cases, which histologically were shown to be leukæmia, have been described where the capsules of the gland were not respected by the lymphoid cells and where the growth had in this respect a close resemblance to lymphosarcoma. In this connexion we might note that Banti[5] regards lymphatic leukæmia as a sarcomatosis, the involvement of the capsule of the gland being but a stage in the progress of the disease.

It is probably, then, only the first (leukæmic) type of glandular enlargement in Hodgkin's disease that takes on a lymphosarcomatous growth; and certainly one would not look for lymphosarcoma developing in the second type, where the tendency is rather to destruction of lymphoid elements by the overgrowth of the stroma tissue. The case, however, which I have recorded was not a lymphosarcoma but a large-celled sarcoma—i.e., an overgrowth of stroma cell rather than lymphoid cell—but whether or not it commenced as a Hodgkin's disease (of the fibroid type) is now impossible to say. If the glands first affected showed originally this change it had been entirely obliterated by the sarcomatous growth, and the glands that are in the process of being invaded by sarcomatous growth show no sign of fibrosis; they are, indeed, apparently normal glands invaded by a large round-celled sarcoma. So that if the sarcomatous process started primarily from glands affected with a chronic fibrosis (Hodgkin's disease) it advanced to normal glands as a sarcoma pure and simple. While confined to the glands the mode of growth was more that of a Hodgkin's disease in that it involved adjacent glands—those of both sides of the neck and in the axillæ—before the surrounding tissues became infiltrated. But when once the limits of the glands were passed the growth was by continuity, extending in various directions and infiltrating and destroying adjacent tissue. There were no metastases, though carefully looked for at the post-mortem examination.

It might, of course, be suggested that the primary lesion in this case was not in a gland but in the connective tissue somewhere about the pharynx, with secondary involvement of glands. If that were so the primary lesion must have been of very slow growth, as there was no sign of the existence of such a growth within 12 months of the time the enlarged glands were visible.

What may be the relationship of the second (fibroid) type of Hodgkin's disease and sarcoma is a question difficult to answer. As we have already seen, Banti maintains that lymphatic leukæmia and pseudo-leukæmia (leukæmic type) are the same disease and of the nature of a sarcomatosis. The increase of the adenoid tissue throughout the body in these conditions is therefore neoplastic and not hyperplastic. Now if there is any truth in this it should be equally true for the second (fibroid) type of pseudo-leukæmia, where the diseased process is essentially one of connective tissue cells. And this type of growth has its own malignancy in the form of metastases in the spleen, liver, and other organs, these secondary growths always repeating the fibroid structure of the primary lesion. MacCallum[6] has recently recorded two cases of this fibroid form of pseudo-leukæmia where the lungs were invaded by extension from the bronchial glands, the growth having broken through the capsule of the gland and producing a diffuse infiltration of the lung with this tumour-like tissue. Such cases would seem to show some affinity with the true sarcoma and they at least suggest a neoplastic rather than a hyperplastic origin for the new growth.

In concluding, I wish to express my indebtedness to Dr. Mary Hannay for the careful histological examination which she has made of the tissues in this case, and to Professor Robert Muir who has been kind enough to examine the sections and who confirms the statements regarding the nature of the tumour growth.

Glasgow.

THE PREMONITORY SIGNS OF ARTERIO-SCLEROSIS.

By ALFRED S. GUBB, M.D. PARIS, M.R.C.S. ENG., L.R.C.P. LOND.

ONE hears a good deal about arterio-sclerosis nowadays, and although the meaning of the term is clear enough as indicating a particular morbid tendency the descriptions given of its manifestations vary so greatly that it becomes difficult to form a concrete idea of its clinical significance. Arterio-sclerosis is conceded to be a common condition, examples thereof coming under one's notice daily; in fact, it is stated to be one of the commonest causes of death after middle age, so that the more we know about it the better, especially in view of the fact that if diagnosed before irreparable mischief has been caused its effects may be greatly attenuated and its progress almost indefinitely delayed by appropriate treatment, including diet, medication, and modified habits of life.

Arterio-sclerosis is not "one and indivisible," in the sense that it practically never involves all the arteries to the same extent but weighs especially on individual systems—renal, cerebral, cardiac, hepatic, &c.—creating a morbid state the manifestations whereof vary according to the region involved. We see a good deal of arterio-sclerosis at thermal stations, usually at a sufficiently advanced period for it to be productive of more or less grave physiological disturbance, a period at which, indeed, it is much more interesting from a clinical than from a therapeutical point of view. One only regrets not having had the opportunity of intervening at an earlier date, at a time when it would have been possible to avert, or at any rate to postpone, the structural changes that have thrown the organism out of gear. This fact emphasises the importance of an early recognition of the changes generically described as arterio-sclerosis, which with due attention would be possible.

The tendency to arterio-sclerosis is markedly influenced by heredity, although it can be acquired by certain habits of life. We find that a large proportion of these subjects are the offspring of arthritic or gouty parents who have succumbed to renal, cardiac, or cerebral arterio-sclerosis, and in these the premonitory signs of the degeneration may be observed quite early in life in the form of attacks of epistaxis, migraine, premature baldness, &c. The initial symptoms are such as one would expect to result from slight variable disturbances of this or that local circulation due to changes in the walls of the vessels that interfere with the automatic regulation of the circulation. Any accidental strain thrown on the damaged organ or system accentuates these disturbances and renders them for the time being more prominent. The constitutional symptoms comprise a slackening of the intellectual powers with inability to concentrate the attention and diminished energy for work. The subject is rapidly fatigued and if the effort be maintained headache and exhaustion follow. This tendency to fatigue is visible in the drawn features and psychical depression; in fact, we get a condition which might clinically be described as neurasthenia. Under stress of excitement or physical fatigue there may even be temporary amnesia or disturbance of articulation. This state is associated with a peculiar sensitiveness to the action of alcohol and tobacco which even in reduced quantities give rise to distressing sensations that worry the patient and render him morbidly irritable. Irritability of temper is a fairly constant manifestation, especially as the victim sooner or later becomes aware that his judgment is not as sound as it used to be, that self-control is lessened, and that the burden of responsibility weighs more heavily upon him. Persons naturally vivacious become somnolent or apathetic. More or less persistent headache is a common feature in the early stages of arterio-sclerosis. Already noticeable on awakening in the morning it is apt to get worse as the hours go by and ere the day's work is over it may assume a throbbing character. It is specially apt to be caused or intensified by intellectual effort, by alcohol, or by excitement of any kind. The significance of headache as a manifestation of arterio-sclerosis can obviously only be determined by a process of exclusion, seeing that it is common to so many other morbid conditions.

Sensory disturbances in one form or another are fairly constant. They may take the form of neuralgia: intercostal, facial, &c., or the patient may complain of tingling or numbness in the limbs, associated or not with slight evanescent paresis of an arm or a leg, such paresis being sometimes accompanied by pain without tenderness in the whole limb. Of all the premonitory signs of arterio-sclerosis *quâ* atheroma giddiness is, perhaps, the most constant and characteristic. Although characteristic, the giddiness only possesses clinical significance when of daily occurrence. It may be occasioned by mere change of position, more particularly from the recumbent to the erect, and in its slight early form it may not amount to more than a feeling of hesitation, a mere lack of stability with a tendency for things to "swim" associated with some mental anxiety. Inasmuch as this instability is not infrequently associated with singing and other musical noises in the ears, it is necessary to eliminate the possibility of the symptoms being due to Ménière's disease or other affection of the auditory apparatus. It may be remarked, indeed, in respect of the pleiades of premonitory signs of arterio-sclerosis that they are only of importance when after careful investigation no other explanation is forthcoming of their presence, since none of them is absolutely pathognomonic of the condition in its early stage.

Disturbances of sleep are common, although genuine insomnia is the exception. Sleep is uneasy, less deep, and consequently less refreshing than formerly. The subject has to coax somnolence and resorts to various devices with that object in view. Then, too, he is morbidly sensitive to the action of stimulants, especially tobacco and champagne, and exciting emotions, whether pleasant or the reverse. This sensitiveness to tobacco, coffee, tea, &c., in persons previously accustomed to unfettered indulgence therein is very suggestive and should excite suspicion.

Mental depression *quâ* neurasthenia is always present in some degree. It may be the direct, immediate result of the disturbance of cerebral circulation or it may be consequent upon the wearying influence of the visceral troubles. The supervention of neurasthenia in a person between 45 and 50 years of age who has never before displayed any neurotic stigmata is highly suggestive, especially when it is characterised by permanence. The depression begotten of business worries and emotional disturbance is ephemeral, whereas that due to organic changes, though variable in degree, is naturally persistent. It may be stated in general that neurasthenia supervening in middle-aged subjects is a symptom of grave prognostic significance, but here again it is only in the absence of other obvious explanation, such as some serious organic lesion or in the initial stage of general paralysis, that it can be regarded as indicative of arterio-sclerosis; in other words, the latter is only one of the possible causes of neurasthenia in the middle-aged.

Among the slight signs that usher in arterio-sclerosis affecting the aorta Dr. Capiello of Naples calls attention to a peculiar sensation in the palm of the hand experienced when pressure is made on the radial artery to the extent of arresting pulsation. Thereupon the subject feels a "breath" or a tingling along the palmar arch. This, however, is a sign of aortic insufficiency rather than of arterio-sclerosis pure and simple, and is therefore only obtainable at an advanced stage. A simple way of determining the existence of general arterio-sclerosis is by estimating what French physiologists call the "stability" of the pulse. Under normal conditions the pulse-rate is eight or ten per minute higher in the erect than in the recumbent position, and when observation shows that such is not the case we may infer that the blood pressure is markedly above normal, while if the ratio be reversed it may be taken as proved that not only is the arterial pressure unduly high but that arterio-sclerosis has reached the stage of giving rise to definite organic disease, an assumption which is confirmed should we find that the heart apex is displaced to the left.

Exaggerated arterial tension with a small, hard, thready but regular pulse is a recognised sign of confirmed arterio-sclerosis, but in minor degrees it also constitutes an early premonitory sign; indeed, some weighty authorities believe that actual changes in the arterial walls are preceded by prolonged exposure to the ill-effects of persistent high pressure, what Huchard calls the præsclerous period, such hypertension being due to spasmodic contraction of the arterioles probably dependent on toxic irritation of the vaso-motor system. High arterial tension, it is true, is commonly associated with chronic renal lesions, but the presence of the latter by no means excludes the possibility of the mischief being due to arterio-sclerosis; indeed, the renal lesion may be, and often is, due to local arterio-sclerosis. When in addition to an abnormally high blood pressure we get some of the other signs just mentioned there is a strong presumption in favour of the existence of arterio-sclerosis.

Aix-les-Bains, Savoie.

A CONSIDERATION OF THE STATE OF THE AUTONOMIC NERVOUS SYSTEM IN ACUTE SURGICAL CONDITIONS.*

BY ALBERT J. WALTON, F.R.C.S. ENG., L.R.C.P. LOND., M.B., B.S., B.SC. LOND.,
SURGICAL REGISTRAR, LONDON HOSPITAL.

(Concluded from p. 25.)

Injection of fluids.—The injection of fluids is useful in all these cases of lowered blood pressure. It acts mechanically by increasing the amount of fluid in the circulation. It is specially useful in all cases of shock, for here not only is the pressure lowered by dilatation of the vessels of the splanchnic area, but in this condition there has probably been loss of fluid, not only by hæmorrhage and escape of inflammatory fluids, but probably, in the case of abdominal operations, by the evaporation of fluid from the surfaces, as shown by the increase of specific gravity of the blood. At the same time the abnormal viscosity of the blood is, by the increase of fluid, decreased to normal, and the circulation thus aided. The main methods of its administration have been considered in the treatment with suprarenal extract, and of these the continuous rectal infusion proves to be the most satisfactory and the most readily worked. One other method may be used, and that is the introduction of one or more pints into the peritoneal cavity during the course of the operation; not only does this cause an immediate rise of blood pressure, but it has been proved to lead to a marked leucocytosis, which, in a condition of general peritonitis, is greatly to be desired. It must be remembered that this method of treatment may be readily overdone, and, after its re-introduction by Mayo Robson in 1893, there was a tendency to administer it in too large quantities—up to a few years ago from 10 to 12 pints were often administered. If such be done there is a great likelihood of death being caused by œdema of the lungs. It may be stated that, by intravenous methods, not more than three pints should ever be given, and by continuous rectal infusion not more than from five to eight pints. By the rectal method much less harm is likely to be done, for when the normal pressure is reached the excess of fluid is returned and no more is absorbed. Even should it be absorbed, time is given for its excretion to take place by the kidneys.

Mechanical methods.—But little further need be said concerning these; most of the methods have already been considered under the heading of preventive treatment, but, in addition to these, considerable benefit may be derived from the position of the patient. By raising the foot end of the bed 18 inches to 2 feet in a kind of inverted Fowler's position the blood is mechanically tilted out of the portal system to the heart and brain. This position is especially useful, as it aids considerably in the retention and absorption of fluid administered by the rectum. It is, however, sometimes difficult to determine what course to adopt in cases of acute peritonitis. In them the septic condition is often localised to the pelvis or lower part of the abdomen and thus it is desirable to have the patient placed with the head raised (Fowler's position), so as to aid drainage and to prevent the spread of the sepsis upwards. It must be remembered that such drainage must be brought about early, for after about 24 hours it is no longer possible to alter the site of the fluid by changing the position of the patient owing to the formation of adhesions. The general condition must largely influence one in determining the method to be adopted. If the shock is the most marked factor the patient should be placed with the head down; if not, in the Fowler's position. In doubtful cases it is often best to place him in the first position for two or three hours, then to lower him until he is horizontal; after a few more hours he may be placed in Fowler's position.

Summary of Treatment.

Whenever preventive treatment is possible everything should be done to perfect the patient's general condition; no powerful purgatives should be given, and light, easily assimilated diet should be administered to within a few hours of operation. Throughout the course of the operation and for some hours afterwards blood pressure tracings should be taken; without their aid the patient's condition may not be readily recognised until it has become serious, while if a careful record be kept not only are the slightest variations made visible but the patient's reaction to the various steps in the operation or to any curative measures is readily estimated. They can easily be taken at the wrist without, in the majority of cases, in any way interfering with the surgeon. In any large hospital this duty may be undertaken by a dresser. The methods of taking a reading are easily learnt and may be quickly performed, and many of the after-operation records may be safely left in the hands of an intelligent nurse. As regards the anæsthetic in such cases ether should be always chosen if possible. If this cannot be done and the operation required is one below the diaphragm spinal anæsthesia is by far the best method. Chloroform should be used as seldom as possible. In head operations a quarter of a grain of morphine as a preliminary lessens the shock and allows of less anæsthetic being given.

In operations upon the extremities a great future seems to lie in the use of Crile's pneumatic suit, and one would like to see it brought into far more general use; with it the blood pressure can be perfectly controlled and shock almost completely prevented. In operations upon the abdomen it may be used on the limbs but with less chance of success.

In no case should any form of stimulant, either brandy, strychnine, or ether, be administered previous to, or during the course of, an operation. This is a matter upon which much stress should be laid, for at present it is so often the case that as soon as any signs of shock develop the patient is given 1-60th of a grain of strychnine hypodermically; if the condition does not improve a second 1-60th of a grain is given shortly afterwards. If the centres are not entirely exhausted by this time he is returned to bed and a 1-60th combined with brandy is given until they are. Nothing can be more likely to bring about the very condition one wishes to avoid.

If signs of shock begin to develop, as shown by the fall in pressure, 15 minims of the B.P. hypodermic injection of ergot should be given, which may be repeated after its effects begin to fail, which will probably be in about 20 minutes. If the fall continues in spite of it a vein should be opened and the patient infused; for this purpose one drachm of the liquid extract of suprarenal (adrenalin) to one pint of saline solution should be used. If the operation be an abdominal one, saline solution may be poured into the peritoneal cavity, but in the majority of cases this will be unnecessary.

During the course of operation a 2 to 4 per cent. solution of cocaine should be injected into any large nerve before it is divided, and exposure or handling of deep-seated organs, especially the abdominal viscera, should be avoided as much as possible. The temperature of the operating theatre should be kept warm but not sufficiently hot to cause excessive sweating of the patient. After the operation is completed a tight abdominal binder should be applied so as to contract the splanchnic area as much as possible. When the patient has been returned to bed the following method may be carried out by routine provided none of its steps have had to be undertaken during the course of the operation. The patient is immediately given a quarter of a grain of morphine, so that on recovering from the effects of the anæsthetic the pain will not be appreciated by the controlling centres. At the same time the foot of the bed is raised about 1½ to 2 feet higher than the head end. 15 minims of ergot are now injected subcutaneously while the saline solution and suprarenal extract for continuous injection by the rectum are being prepared. As soon as possible this is commenced, being administered by the method previously described and allowed to run continuously at the rate of one pint per hour until either the fluid is rejected or five to six pints have been administered. If the case be a septic peritonitis the foot of the bed is lowered after two or three hours, and after a further two or three hours the head is raised.

---

* A paper read before the London Hospital Medical Society. (The superior figures refer to the bibliography at the end of the article.)

The difference in the results gained by this method and those where stimulants are alone given is most marked clinically, and the different bearings of the two upon the blood pressure, and consequently upon the condition of shock, are well shown in the previous figures.

2. CHANGES IN THE LOCAL NERVOUS SYSTEM OF THE INTESTINES.

Just as multiple afferent impulses to the centres governing the muscular apparatus of the vessels cause their exhaustion with loss of tone to the vessels and consequent dilatation, so also multiple impulses from the intestines cause exhaustion of that apparatus governing the muscular movements of their walls with consequent paralysis of these walls and apparent obstruction. These impulses may arise in the gut itself before operation when they are probably toxic in nature. Such a condition is well seen in acute localised or general peritonitis, which, in the majority of cases, is associated with loss of tone and dilatation of the intestinal canal, as shown by obstinate constipation. In other cases operation, with its associated and necessary trauma, seems to be the causative factor, and cases arise after operation where symptoms of dilatation of the intestines are presented, the so-called "ileus" or "peritonism," which may proceed to the death of the patient, and where post-mortem, on the most careful examination, not the slightest evidence of either peritonitis or obstruction can be discovered. The pathology of such a condition has been but little understood and its very existence has been doubted, some even suggesting that it has rather been an excuse for death given by the surgeon, who does not wish peritonitis or other complications to occur. But that such a state does exist I have no doubt. I have now either personally carried out, or seen performed, post-mortem examinations on several cases, operated on by different surgeons, where clinically the condition has closely resembled acute peritonitis associated with dilatation and paralysis of the intestine, and yet post mortem nothing of this nature could be discovered. The small intestine was greatly dilated, but on tracing down this dilated part no evidence of obstruction was found, even where the dilatation ceased abruptly.

Cases throwing light upon this condition are those of certain nervous diseases, such as disseminated sclerosis. Here the patient may be seized with all the signs of acute intestinal obstruction, but at operation no organic lesion is found. They may even go on to death, and at the post-mortem examination no lesion of any sort that would account for the symptoms may be discernible. The following is such a case. I have to thank Dr. L. A. Smith for permission to publish it.

The patient, aged 18 years, had been attending hospital several times with disseminated sclerosis, which had lasted for five years. He was admitted complaining of abdominal pain and absolute constipation, which had been present for the last two days. Since the onset he had vomited eight times. There was marked spasticity of the legs, with increased reflexes. There were rather coarse irregular tremors of the hands and a slight lateral nystagmus. The speech appeared to be normal. The pulse was 114. The abdomen was considerably distended but was not rigid. No peristaltic waves were seen and there was no area of marked tenderness. The temperature was 98° F. The tongue was dry, brown, and furred. Three enemata were followed by no result. The patient was seen by a surgeon, who decided to operate. An opening was made in the mid line about three inches in length and below the umbilicus. The small intestines were markedly distended but the walls were not injected. There was no excess of fluid and no evidence of obstruction could be found. The abdominal wound was sewn up. No result followed the administration of strychnine hypodermically, with calomel and sulphates by the mouth, with several enemata. The patient died 12 hours after operation. Post mortem the intestines were found to be distended but there was no evidence of obstruction of any sort, the lumen of the gut being perfectly clear. Beyond a little adhesive peritonitis around the wound nothing could be discovered locally to account for the condition.

Physiology of peristalsis.—In the normal intestines movements of two kinds occur. Firstly, swaying pendulum movements, which, according to Bayliss and Starling, are myogenic in origin and are but little concerned in the onward movements of the intestinal contents. The second variety, or true peristaltic movements, consist of a slowly moving ring of contraction, which is immediately preceded by a zone of dilatation, the whole passing down the gut from above. At times the ring of contraction does not take place behind the mass of food but in the centre or other parts, so that the mass is divided into two or more portions—segmentation movements; the areas thus formed may unite again from relaxation of the ring of contraction to form a continuous mass (Cannon).[8] These movements are independent of all central nervous control and take place as readily, if not better, after all the extrinsic nervous connexions have been divided. From this it may be assumed that they are either myotonic or due to the influence of some local nervous centres. If cocaine and nicotine, which are known to paralyse all nerve cells, be applied to the intestines all peristalsis stops, and although it can be induced by local stimulation it cannot be propagated. If now a portion of intestine be excised, turned round and sutured into position so that what was formerly the upper end is now lowest, it is found that all peristaltic movement is stopped at this point, a functional obstruction having been caused, although the lumen is perfectly clear. This point is of considerable importance in operative work upon the intestines, for it is probably the factor chiefly concerned in the persistence or origin of obstructive symptoms after a lateral anastomosis has been formed which is not isoperistaltic.

From these experiments it has been deduced that the peristalsis is dependent upon the influence of some local nerve plexus, and that of Auerbach is the one which is usually selected for this honour. The central nervous system, however, exercises some control, for if the splanchnic nerves be cut it is found that the movements are augmented, whilst if the peripheral ends of these nerves be stimulated peristalsis is decreased or arrested. On the other hand, stimulation of the peripheral end of the vagus increases them.

The recent researches of Hertz[9] have shown that the rate of peristalsis is such that in the normal state the food usually takes about four hours to reach the cæcum, but under abnormal conditions this may be much altered. On reaching the ileo-cæcal valve a slight stop occurs. Keith suggested, on anatomical grounds, that a true sphincter existed at this point, and Elliott[10] has since proved that such a sphincter does exist here, the action of which is controlled by the splanchnic nerves; when these are cut it becomes permanently relaxed and food passes regularly through.

Jacobi[11] has shown that in the large intestine the movements are precisely similar to those in the small intestine, with the exception that antiperistaltic waves are much more marked. The peristaltic waves are much slower in their progress; thus Hertz[9] has found that about four and a half hours usually elapse while the food passes from the cæcum to the sigmoid flexure. During sleep the movements are even slower. In the large intestine the lumbar and sacral nerves (second, third, and fourth) take the place of the vagus and splanchnics. Thus movements of the intestine are started by some local stimulation applied to the mucous membrane, and are propagated by the control of a local nervous mechanism which may be regarded as the plexus of Auerbach.

The question now arises, What causes the abeyance of these movements in a condition of peritonism? On this point two important pieces of work have been done. Pawlow has shown that all movements of the intestine are markedly decreased by stimulation of many sensory nerves, and may indeed be completely inhibited by this means. From our present point of view this is of considerable interest, for we have both the dilatation of vessels in shock and the loss of peristalsis, which is the cause of dilatation of the intestines, set up by a similar cause—namely, excessive sensory stimulation.

Cannon and Murphy[12] have shown that peristalsis in the rabbit, as shown by movements of bismuth recorded on the screen, is not affected by prolonged etherisation, exposure to the air, or cooling of the intestines. But a very marked delay occurs after all manipulation.

From these experiments I would suggest that we have here a process exactly similar to that concerned in shock. Just as primary stimulation of a sensory nerve causes a rise in blood pressure, so peristaltic movements under normal conditions are initiated by some local stimulation, usually a mass of food within the lumen of the gut, and just as prolonged stimulation of the sensory nerves leads to exhaustion of the vaso-motor centres with a subsequent fall of blood pressure, so prolonged stimulation of the gut caused by surgical manipulation leads to exhaustion of the local centres situated in Auerbach's plexus, with failure of propagation of all peristaltic waves and the onset of ileus.

Another factor, and one which is more marked in those cases where paralytic distension of the gut occurs before operation, as in acute general peritonitis, is the effect of toxins upon the local centres. It has been shown experimentally that peristaltic waves are inhibited by any toxic state of the peritoneum, and indeed such is well known clinically, the toxin in this case having the same effect upon the local centres as it does upon the vaso-motor centres in producing shock.

Treatment.

Two distinct classes of case have to be considered. Firstly, those in which, before operation is undertaken, the cause of the condition, usually toxic in nature, has been present, and where at operation, although no obstruction be present, yet the intestine is found to be considerably dilated. Secondly, those in which some abdominal operation has been undertaken, and later symptoms of intestinal obstruction intervene, yet there is reason to believe that no obstructive lesion is present and that no peritonitis has occurred.

In the first class of case the treatment will in the great majority be operative. Excluding those rarer cases, such as the one already described, where the condition is due to some previously existing nervous disease, the state of the intestines is dependent upon some locally acting cause, such as acute peritonitis, which will usually call for operation. The abdomen having been opened the peritoneum is dealt with by the method preferred by the individual surgeon, either simply drained or washed out. If the intestines are found to be greatly distended they also must be drained; the presence of their toxic contents is largely accountable for the condition of paralysis of the gut wall and is also seriously affecting the patient's general condition. If there be any organic obstruction it is one of the rules of abdominal surgery that the abdomen should not be closed until the intestines have been emptied. In the same way, if the obstruction be only paralytic in nature there is a much greater likelihood of their return to a normal condition if the cause has been previously removed. This may be brought about by simple puncture of a coil of gut over a receiver but by this means it will, as a rule, only be found possible to empty one or at most two coils of gut. The method introduced by Moynihan[13] for emptying the gut in cases of acute obstruction will be found to be the most serviceable. A glass tube eight inches long has a rubber tube attached at one end, the other is cut obliquely; this end is passed through a small opening in the anti-mesenteric border of the gut, which is then threaded on to the tube; about six feet can thus be passed. As the tube is passed along the gut is, of course, emptied, the contents flowing along the rubber tube to the pail beneath. The glass tube is now removed and the opening in the gut sutured.

As regards the after-treatment in such cases many believe that no attempt should be made to empty the intestines for some days. They claim that but very few of these cases are really general peritonitis and that by keeping the intestines at rest there is much greater chance of limiting the inflammatory process. If this be correct the danger of so leaving them at rest will be very slight if they have been efficiently drained during the operation by the method given above. If, however, it be believed, as it is by many, that there is more likelihood of a successful issue if the bowels be opened as soon as possible those methods may be undertaken which will be described for the second class of case.

In the second class of case operation is not desirable. There may be marked dilatation of the gut but, as a rule, no evidence of inflammatory changes, and if the symptoms have set in soon after operation, as they usually do, there is but little probability that any band can have yet formed which has led to organic obstruction. The only question is whether any obstruction present originally has been overlooked at the primary operation; but in the majority of this type of case the primary operation was for some condition where the symptoms were very unlikely to have been due to this cause and in such it may be recognised that the subsequent symptoms are due to a paralysis of the muscular wall, due probably to the exhaustion of the local centres by the trauma which has, of necessity, been applied during the primary operation. In them some form of treatment will have to be undertaken which will overcome this condition and lead to a speedy return of the intestinal movements.

The treatment may be grouped under three main headings: the administration of drugs by the mouth, various forms of enemata, and subcutaneous injection of drugs. Other means have of late been used whereby drugs, such as magnesium sulphate in solution, have been inserted into the intestine during the operation. In some cases, where the lesion is fairly high up, this is of use, but if there be much dilatation the correct treatment will consist in emptying the intestines while the patient is on the table, while if they are not dilated the drug will either not be required or will be excreted before the symptoms of ileus make their appearance. After they have been excreted this condition may indeed be more likely to occur owing to the increased irritation caused by the presence of the drug.

Administration of drugs by the mouth.—The most usual method of treatment in abdominal cases, where early peristalsis is required, is to give the patient, after operation, calomel in one grain doses every hour for from four to six hours, the last dose being followed by some simple saline mixture, such as the sulphates of sodium and magnesium. This is usually combined with strychnine subcutaneously. Such a method of treatment is very useful in simple abdominal cases as a preventive rather than a curative measure. If, however, severe vomiting be present it of course fails in its object. Such vomiting is nearly always found in cases of ileus, and even if not, these drugs are found to fail in their action, the distension in many cases only appearing to increase. This line of treatment, moreover, labours under the disadvantage that the strychnine administered acts, as previously shown, in a most detrimental way upon the condition of shock, and thus this portion, at any rate, should be omitted.

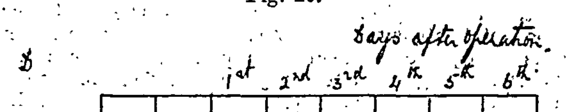
Enemata.—Of these but little need be said; their use is most advantageous and in most cases of distension the administration of a turpentine or asafœtida enema will be found to bring about speedy relief. Their use as a means of determining whether true obstruction be present or not is also invaluable. In cases of true ileus, however, they are often found to fail in their purpose, but they should certainly be combined with any other form of treatment that may be adopted. Their action is probably to stimulate the muscle of the lower gut directly and thus to increase peristalsis, but from the fact that they fail in ileus it seems probable that they are incapable of actually initiating the peristaltic wave, possibly because they do not pass up high enough to reach the true seat of the lesion.

Subcutaneous injection of drugs.—The favourite of these is *strychnine*, which is usually given in 1-60th of a grain doses four-hourly, but it is doubtful if any marked effect on the intestinal movements follows its use and for the reasons mentioned above it should not be used. The explanation of its failure to act is probably that its action is purely that of a stimulant to the exhausted centres in Auerbach's plexus and, as with the vaso-motor centres, stimulation of them, when exhausted, is not likely to be followed by any action but rather by further exhaustion. *Atropine.*—This drug acts by removing the inhibitory action of the splanchnics but in the condition of ileus the lesion is lower down, and thus it would scarcely be expected to have any marked influence. It also acts by allaying spasmodic contractions and converting them into slower, more powerful, and regular movements, and for this reason has been given in cases of mechanical obstruction

(Bosch)[17] with good results. Clinically it is found to be of no value in ileus. *Eserine salicylate.*—Recognising the seat of the lesion in this condition it seems that if a drug could be secured which, given hypodermically, would act directly upon the muscular tissue of the intestine in the same way that ergot and suprarenal act upon the vessels locally, then the intestines might be made to act until the exhaustion of the centres was overcome, and they were again capable of taking up their functions. Such a drug is present in eserine or physostigmine. The use of it for these conditions was first advocated by Arndt,[14] who administered it after operations. He injected subcutaneously 0·001 gramme and repeated this dose if necessary. He has never noticed any unpleasant effects, and has reported several successful cases. He noticed one important distinction. In several cases there was marked meteorism which was not allayed by the use of this drug. He found in these that there was gastric distension, and that eserine did not affect the movements of this viscus. If, however, the stomach were emptied, or, preferably, washed out at the same time, relief followed. A large number of cases have been treated by Vogel[16] in the same manner, and he expresses a firm belief in its efficacy. On the other hand, Pankow[15] states that it does not relieve meteorism, but he used it in all varieties of cases, and, as will be seen presently, the normal intestine is not affected by it.

A few months ago I had the opportunity of using this drug considerably, trying first of all its action in normal people, but found that it had practically no effect. In severe abdominal lesions its action was, however, most marked. Fig. 10 is a chart drawn up to show the average number of times the bowels were opened in each patient every day after the operation. These were all acute abdominal lesions, and the averages were made up from 15 cases treated with eserine and 25 treated without. In all cases the salicylate was used, as this is the most soluble and is readily obtained. The cases treated with eserine are marked with a continuous line and those without by an interrupted line, but during the first three days after operation the bowels were in the latter group only opened with enemata. It will be noticed that the drug has a very marked effect, but that its action is best marked after one or two days. In the first few cases 1-50th of a grain was given every four hours and repeated until six doses had been administered. In several of these the results were rather too severe, and a mixture of bismuth and opium had to be given to check the resulting diarrhœa. In the later cases only 1-100th of a grain was given, and it was found that in the majority of cases this could be safely administered for six doses. There seems, however, to be considerable variation in the way different patients are affected.

Fig. 10.



The different conditions in patients treated with and without eserine. Continuous line = with eserine. Interrupted line = without eserine. Compiled from acute abdominal cases only. 15 with and 25 without eserine.

As regards the action of the drug, Hale White[18] states that the muscular coat of the intestines is directly stimulated by the action of the eserine circulating through it; but it is not decided whether it is the muscular fibres or the terminations of the nerves in them which are affected. In either case it will be seen that the part stimulated lies lower than the exhausted part, which is left untouched and allowed to recover.

The reason why the drug does not act in health is at first sight difficult to understand, but it is probably due to the fact that until the local centres are paralysed, as in ileus, the muscular action is kept in abeyance by impulses passing down the splanchnic nerves; when the local centres are paralysed, these, of course, have no effect. Moreover, in these cases there is usually considerable shock, and hence but few impulses will pass down the splanchnics.

Here may be mentioned the fact that spinal anæsthesia is often followed by profuse diarrhœa, but this occurs as a rule either during or soon after the operation, and is probably due to the removal of the inhibitory impulses passing to the large gut along the second, third, and fourth sacral nerves, and thus probably, except as a preventive measure, will be of but little benefit in true ileus.

Summary of Treatment.

In cases of acute paralysis, due to some toxic condition present within the peritoneum, the intestines should be drained as freely as possible during the course of the operation undertaken for the relief of the local condition. In all other conditions no operation is called for, and, since the state of the intestines depends upon the exhaustion of the centres, any form of stimulation is only likely to do harm. Immediately after operation, injection of 1-100th of a grain of eserine salicylate should be given, which may be continued four-hourly until six doses have been given. If no action of the bowels occurs next day a turpentine enema may be given. This line of treatment of course applies only to those cases where it is considered beneficial to keep the bowels open. The question as to when to, and when not to, open the bowels in acute abdominal conditions is too long a one to be considered now. It may be stated then that the effects of any severe operation upon the autonomic nervous system consists of an exhaustion of its centres, both central and local, and that any treatment must aim at procuring rest of these centres. Since in man exhaustion always occurs first in the nervous system treatment of the symptoms should aim at stimulating the local organs so that they may act alone until such time as the centres are again able to undertake the control.

In conclusion, I must acknowledge my indebtedness to the valuable work of Crile and Lockhart Mummery, upon which the first part of this paper, that on "shock," is largely based.

London Hospital, E.

AN ORIGINAL METHOD OF FACILITATING INTRA-LARYNGEAL OPERATIONS,

TOGETHER WITH FOUR CASES OF INNOCENT GROWTHS OF THE VOCAL CORD REMOVED.

BY CYRIL HORSFORD, M.D. EDIN., F.R.C.S. ENG.,
SENIOR REGISTRAR, CENTRAL LONDON THROAT AND EAR HOSPITAL;
HONORARY SURGEON, THROAT AND EAR DEPARTMENT,
ST. PANCRAS AND NORTHERN DISPENSARY;
HONORARY LARYNGOLOGIST, LONDON
COLLEGE OF MUSIC.

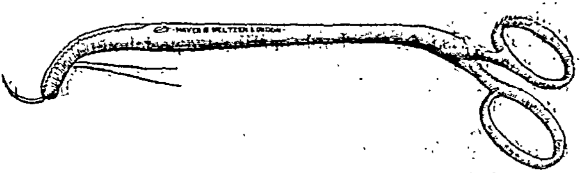
THERE can be no doubt that there is scarcely a region of the body which presents such a difficult field for the exercise of surgical manipulation as the cavity of the larynx. This fact is generally admitted even by those who practise specially in this region of the body. An inquiry into the causes of the difficulty may not be out of place here. These are: 1. The inability to obtain adequate experience. Intra-laryngeal operations occupy a very small part of the average laryngologist's duties, for in the early days of the specialty there was probably much accumulated material, whereas now the experience gained by each is scarcely sufficient to overcome the difficulties to be considered. 2. The obstacles provided by nature. The larynx being the gateway to one of the vital regions of the body nature has provided a most effective barrier to the intrusions of foreign bodies, including the surgeon's instruments. Beginning at the true glottis and extending upwards there is a series of most perfect sphincters, any of which can effectually prohibit intra-laryngeal manipulation. This action is dependent on a highly sensitive mucous membrane and an equally active reflex mechanism. Further, the larynx is so situated that one's best and often only guide into it is a powerful light and an inverted image. In the opinion of the writer, however, the most annoying obstacle is the lid or epiglottis, which sometimes so overhangs as to render a view of the interior of the larynx impossible. The position of the epiglottis varies in every case, and as it is often a bugbear to the laryngologist any simple method of effectually getting over the difficulty should be welcomed by the profession. The epiglottis, as I have suggested, has always been recognised as being one of the main difficulties both in seeing and in treating the interior of the larynx, and many devices have been introduced to get it out of the way. Most, and probably all, of these have taken the form of some instrument which, when introduced into the glosso-epiglottic fossa or over the epiglottis itself, temporarily lifts up the epiglottis. All these necessitated the continuous use of the hand to hold the instrument while in that position. Whether that hand be one of the operator's or that of his assistant is immaterial, for such a method is obviously unsuitable or inconvenient for facilitating intra-laryngeal operations.

The method which I advocate is to pass a suture through the epiglottis, the ends of which are brought over the centre of the tongue and gripped by a pair of Spencer Wells forceps. The weight only of the forceps will then pull the epiglottis forwards against the root of the tongue and usually quite out of view. The patient then holds the tongue in the ordinary way. The principle is obvious and perfectly simple, yet I feel I am justified in using the word "original," in the title of my paper, for after careful search and inquiry I could not find any evidence that the method had been used before. Sir Felix Semon,[1] however, has recently pointed out that he found that the method was described in a German book about 40 years old, but the author evidently did not succeed in convincing his colleagues of its practicability. The method as I now practise it has evolved through three distinct stages and a description of these stages may be interesting.

The idea first occurred to me in July, 1906, when I adopted it in order to facilitate an operation of exceptional difficulty—namely, the excision of a very tough fibrous web which united the anterior halves of the vocal cords and extended some way down into the cavity of the larynx. The epiglottis was not overhanging, but I wished to get it out of the way because I was using a sharp-pointed Heryng's knife, followed by sharp punch forceps, and it was necessary to get the best view possible. In connexion with this case it was interesting to note that though the greater part of the obstructing tissue was removed it was found impossible to prevent the raw edges of the vocal cords from uniting. The result of apparently so hopeless a case was not without some success. The patient now enjoys active exercise, such as dancing, tennis, and rowing, without getting short of breath, and though absolutely aphonic for eight years, in spite of many trials of voice-production methods, *a* voice has been now produced as the result of vocal exercises. The patient speaks in a deep breathy monotone, but tones can be made varying in pitch to the extent of an octave. In this case I used simply a pair of Spencer Wells forceps curved at the point, with which I held a small curved needle threaded with a horse-hair suture. With the aid of the laryngeal mirror the needle was pushed through the epiglottis from before backwards, the point being then caught by the forceps and drawn through. There was not much difficulty in passing the suture and not the slightest discomfort to the patient, who had already been thoroughly cocainised in preparation for the operation.

The next occasion on which I employed the method was in October, 1907 (see Case 1). The epiglottis in that case being markedly overhanging and accuracy in operating necessary because the patient was a vocalist, I used the needle-holder drawn in Fig. 1, which was made to my design by Messrs. Mayer and Meltzer. Its principle and method of use is similar to that already described in the former case, in which simple forceps were used. The inner surfaces of the points of this instrument are so serrated as to allow the needle to be firmly gripped in any position in which it is placed. This instrument was shown and the method described and demonstrated on a patient at the meeting of the Laryngological Section of the Royal Society of Medicine in December last, and it was very favourably received.[2] In support of this instrument I may say that it will be found useful in all except the most extreme cases, for the only case in which I have failed was one under the care of Dr. William Hill, in which the upper border of the epiglottis was in contact with the posterior wall of the pharynx, for it was then impossible to see the point of the needle after it had been pushed through the epiglottis. Its use is, however, somewhat difficult and is dependent entirely upon a thorough preparation of the patient.

FIG. 1.



In order to render the method acceptable in all cases it was obviously at this stage desirable to facilitate it still further. I therefore had made the instrument shown in Fig. 2 by Messrs. Mayer and Meltzer. It is a modification of Kurz's suturing forceps used for the passage of deep sutures in pelvic surgery. The patient is prepared in the usual way but such complete local anæsthesia is not so necessary as in the former methods. The needle is first

FIG. 2.

[2] Proceedings of the Royal Society of Medicine, vol. i., p. 3.

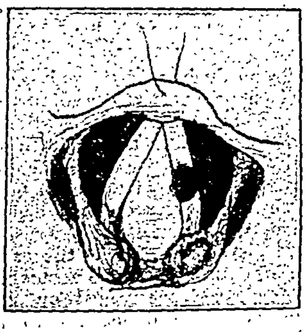
threaded with a long piece of silk and placed in the proximal blade, and with the aid of the laryngeal mirror it is introduced into the throat until the upper border of the epiglottis is seen to pass between the point of the needle and the distal blade. The distal blade only need be watched, for as soon as it is seen to have passed over the upper border of the epiglottis the handles are firmly closed, then opened, and the instrument withdrawn, and it will then be found that the suture has been passed through the epiglottis. As before, the ends are gripped by forceps and an additional pair may be added to increase the weight if necessary. By this means the suture can be passed rapidly, easily, and without any discomfort to the patient. On the occasions on which I have used it the patients have neither strained nor coughed, and when the suture is passed the patient is not conscious of its presence so long as the effect of the cocaine lasts, though in Case 3 there were feelings of nausea which soon passed off. The use of the instrument entails no risk to the patient. The needle is held sufficiently firmly in the proximal blade to prevent it falling out before it is passed and should it do so it falls into the glossal epiglottic fossa only and is easily withdrawn by the thread which is held in the hand. When the blades are closed it is firmly caught in the distal blade and cannot be released until the instrument is withdrawn and the needle turned on its long axis to be liberated; there is, therefore, no risk of its falling into the cavity of the larynx. The epiglottis does not suffer in the least by the passage of the needle, and the only changes which I have observed to follow have been beneficial rather than otherwise, for the simple or adhesive perichondritis which necessarily follows in the neighbourhood of the puncture has resulted in a little stiffening of the epiglottis, which facilitates subsequent intra-laryngeal inspection.

This method of facilitating intra-laryngeal operation is therefore rapid, simple, safe, and painless. The suture occupies no space in the mouth and, unlike other epiglottis lifters (Mount Bleyer's and Escat's), it does not require the assistance of a third hand. It further helps to steady the larynx. Though the shaft of some laryngeal forceps may be used to pull the epiglottis forward during their use it is a decided advantage to be independent of that action, so that the operator may be free to place the forceps in any position he desires to prevent the shaft from hiding the point and obstructing the light. I consider that the method should not be limited to cases of obscured fields of operation but in all cases where the epiglottis in any way hinders a delicate intra-laryngeal manipulation, whether it be cutting or cauterising, especially where a perfect vocal result is desired. This method may also be used simply for diagnosis when other methods of lifting the epiglottis have failed. It may in a few cases be used without the aid of a laryngeal mirror when it is found on depressing the tongue firmly the upper border of the epiglottis can be seen.

This instrument and its use were also demonstrated at the Laryngological Section of the Royal Society of Medicine in April last.[3] As its success depends on the preparation of the patient it may be as well to state my method of procedure. The patient being made calm and comfortable and relieved of all his fears, I spray the pharynx, both surfaces of the soft palate, and the larynx with a 10 per cent. solution of cocaine. Some is then dropped on to both surfaces of the epiglottis with a laryngeal syringe and the patient is encouraged to clear the throat of the superfluous fluid. I very rarely use a swab or brush, and then only when anæsthesia is nearly complete, for it usually produces involuntary coughing, which is unnecessary and should be avoided. It is also advisable to apply to the surfaces of the epiglottis and root of the tongue a little adrenalin, to prevent the possibility of hæmorrhage obscuring the field of operation.

CASE 1.—A single woman, aged 36 years, an amateur vocalist, contralto, consulted me for hoarseness and loss of singing voice. Up to two years previously she had done a good deal of choral singing but since had been obliged to give it up. The vocal difficulty was quite gradual in its onset and occasionally the voice would fail suddenly in the middle of a song. On examination the vocal cords were quite normal in colour, but resting on the upper surface of the left vocal cord was a small spherical tumour, bright red in colour, semitranslucent—both in appearance and size like a small red currant. It had no definite pedicle (see Fig. 3). Clinically it appeared to be a soft fibroma, and was evidently subject to hæmorrhage within its substance, for such an occurrence was demonstrated at her second visit. The epiglottis was markedly overhanging, so much so as to render a complete view of the growth very difficult, and then only on phonation. The growth was removed on Oct. 11th last in the presence of my colleague Mr. W. Stuart-Low and Dr. L. A. Hawkes. Lack's laryngeal forceps were used. The operation was greatly facilitated by the epiglottic suture, which was passed by the epiglottis needle-holder (Fig. 1) without any difficulty or discomfort to the patient. On Dec. 11th this patient was shown at the Laryngological Section of the Royal Society of Medicine when her voice, both singing and speaking, was perfectly clear.[4] She has since resumed her singing.

FIG. 3.



A section of the growth was cut by Dr. V. H. Wyatt Wingrave and his report is as follows: "The growth is of a fibromatous character, highly vascular in parts, the vessels having thin walls. In one region there is lymphocytic infiltration suggestive of an inflammatory process. The surface is squamous epithelium, somewhat thickened and irregular. Its nature is that of a benign fibroma."

CASE 2.—A single woman, aged 29 years, a professional singer, was sent to me for hoarseness and inability to sing. Her history was of considerable interest. She had sung on the music hall stage for the past ten years on and off and had been in the habit of forcing her voice, especially latterly, when she began to be troubled with recurring attacks of huskiness and inability to get easily the upper tones of her voice. The vocal disability became so marked that she was obliged to seek medical aid about 12 months ago, since which time she had been under the treatment of several laryngologists in England and New York for singer's nodes. On one occasion, after several attempts to remove the nodules with forceps, some strong caustic was applied, which unfortunately produced such inflammatory reaction that her singing voice was completely lost for eight months. After a course of six weeks' vocal exercises she resumed her professional work for three weeks in February last, although the voice was still husky, but was then obliged to give up singing, as she regarded it as hopeless. I saw her first on April 1st and found that the nodule of the left cord had disappeared, but on the right cord at the site of election (the junction of the anterior third with the posterior two-thirds) was a very small nodule sharply pointed and evidently one of long standing. There was no laryngitis. On April 4th I removed the nodule with Whistler's forceps and the passage of the epiglottic suture with the epiglottic suture forceps was chiefly responsible for the fact that I was able to effect the removal at my first attempt. The whole operation was completed without the slightest discomfort to the patient and she never coughed or strained once. The epiglottis was not overhanging but I wished to get it entirely out of the way, as I felt it my duty to adopt every means which might facilitate an operation that would make or mar a professional career. For a week I ordered the patient to maintain absolute silence, and at the end of three weeks' rest her singing and speaking voice was absolutely clear and she commenced gentle vocal exercises. In eight weeks from the date of operation I unwillingly permitted her to resume her professional career and she fulfilled with success a week's engagement with two performances nightly at a music hall. She is now studying voice production.

---

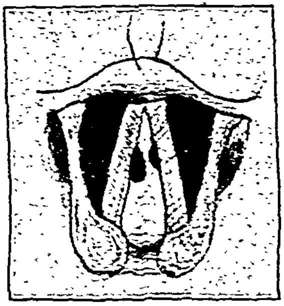
[3] Ibid., vol. i., p. 7.

[4] Ibid.

The operation being one of great difficulty, owing to the smallness of the growth, and the great risk of damaging the vocal cord and so spoiling the voice, Sir Felix Semon, who saw the case before the operation, has kindly permitted me to state that when he examined her again seven weeks after he found the edge of the vocal cord perfect and the voice most satisfactory.

CASE 3.—A man, aged 50 years, an auctioneer, consulted me for hoarseness and increasing difficulty and discomfort in the use of his voice. The hoarseness had been present for many years but had recently become very marked. His occupation necessitated forcible use of his voice in a hot, dry, dusty atmosphere, and he had never had his voice trained for the purpose. On examination I found in his nose no marked obstruction, but it was narrowed by simple hypertrophic rhinitis. There was a great deal of chronic pharyngitis and excessive irritability of the pharynx, which, with an overhanging epiglottis, were some of the causes which rendered a good view of the whole of the interior of the larynx extremely difficult to obtain. So difficult was it that it was not until the third visit that I could make out that in addition to chronic laryngitis there were two soft fibromata at the junction of the anterior third with the posterior two-thirds of each vocal cord. The right was considerably larger than the left, was œdematous and pedunculated, and like the rest of the larynx of a deep red colour (see Fig. 4). On April 13th, 1908, in the presence of Mr. Howard Barrett, I removed the growths with a modified form of Mackenzie's forceps, having greatly improved the view by the epiglottic suture, for which I used the suture forceps (Fig. 2). His voice has greatly improved and at the time of writing he is still under treatment for chronic laryngitis.

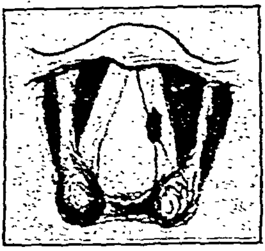
FIG. 4.



Microscopic report by Dr. Wyatt Wingrave is as follows: "A small round mass covered with normal stratified epithelium on its free surface, below which is a loose fibro-vascular network, containing a laminated mass of fibrin, surrounded by a thickened or compressed zone of closely packed white fibres. Immediately surrounding the clot is a layer of epithelioid cells, some of which could be traced into the substance of the fibrin indicating organisation. No pigment could be seen. The growth is evidently produced by endovascular clotting, not a mere extravasation. It is equally probable that the thrombosis occurred in a lymphatic channel; its nature is a thrombosed angio-fibroma."

CASE 4.—This case is recorded because of its clinical and vocal interests, but not in illustration of the above method, for I did not at the time have an instrument suitable for the purpose. A single woman, aged 27 years, a well-known professional vocalist, contralto, came to me complaining of recurring attacks of huskiness, the occasional inability to get some of the higher notes which would suddenly fail, and gradual deterioration of the voice. This condition had lasted about two years, during which she had several mild attacks of laryngitis. She had had previously a good deal of treatment but when she came to me I found in the nose enlarged middle turbinals and chronic suppuration of the left antrum, and in the larynx slight chronic laryngitis, and what may be described clinically as a soft fibroma on the upper surface of the left vocal cord (see Fig. 5). It was situated near the edge of the cord which it partially overlapped and was oval in shape and of a deep red colour. It varied in size and was apparently mobile, although a pedicle could not be observed. Usually during phonation it was safely kept away from the vibrating edge of the cord by the upper current of air, but occasionally an excessive accumulation of mucus on it or blood within it would so increase its weight that a portion of it at least would get suddenly between the vocal cords, causing the vocal disaster above referred to. After improving the condition of the nose I strongly advised removal of the growth, and Dr. StClair Thomson, who had also seen the case, agreed both with the diagnosis and with the treatment recommended. In July, 1907, Dr. A. E. C. Rees being present, I removed the growth with Lack's forceps, and in this case the epiglottis was not a serious hindrance. Her convalescence was somewhat slow because of subsequent laryngitis, which was not surprising as the cords were at the time so affected and the patient breathed through an unhealthy nose. She revived her vocal practice in December and has now resumed her professional career, and is considered to be in better voice than she has ever been, and, what is more important still, it is reliable.

FIG. 5.



The microscopic report by Dr. Wyatt Wingrave was as follows: "A small irregular fragment about 5 by 2 millimetres, consisting almost entirely of thickened stratified epithelium, with a scanty core of vascular connective tissue. There are no signs of heteromitosis but of slight inflammatory process in one part. Nature—a simple papilloma."

Remarks.—The four cases recorded illustrate four different varieties of benign growths of the vocal cord. An important factor in the etiology of all four cases is the over-use or wrong use of the voice. They may be conveniently divided into two groups: Group 1, Singer's node, or corditis tuberosa; and Group 2, soft fibroma, or polypus. Case 2, the only representative of Group 1, can scarcely be described as a new growth, for it is simply an epithelial thickening or corn, the result of attrition with the opposite vocal cord. The condition is common in school board teachers and singers (especially sopranos), and results invariably from failure to acquire that perfect vocal balance which gives the best vocal result with the least effort. The excessive use of the *coup de glotte* and the conditions necessitating forcing of the voice, such as relaxation of the vocal cords, general debility, and noisy surroundings, form the substance of one of the theories of their production. In both conditions there is an excessive accumulation of pressure behind the vocal cords which tend to yield at the centre of their ligamentous portions—that is, the junction of the anterior third with the posterior two-thirds of the whole length of each cord. This results in the bowing inwards of the cords (a condition which should be recognised as the first stage of the tendency of the formation of nodes), so that they meet at one spot before the rest of the cords become perfectly approximated, hence increased friction and growth at that spot.

Another causal theory which tends to explain their occurrence at the site of election rather than their formation is dependent on the following facts. A careful inspection of the surface of a vocal cord during phonation will reveal the tendency of minute droplets of mucus to congregate and coalesce at the seat of election, which is believed to be the nodal point in the compound vibrations of the vocal "string." This is the point of least vibration, and therefore capable of being brought into closer contact with the corresponding point on the opposite cord than the rest of the cord, forming, therefore, the point of greatest friction. The acute nodule, of recent formation consists merely of œdema of the epithelial layers of the cord, and if the cause is persistent there follow epithelial hyperplasia, keratinisation, and lastly, thickening of the adjacent connective tissue. Operative treatment probably becomes necessary when the last two stages have been reached.

With regard to Group 2, laryngeal growths generally are very uncommon, and are shown by hospital statistics to constitute only about 1·25 per cent. of purely laryngeal diseases.[5] Of these papillomata are the most frequent variety, true fibromata being very rare. Of 100 cases of simple growths published by Sir Morell Mackenzie, 10 per cent. were fibromata but only two resembled my cases.[6] Dr. Wyatt Wingrave has, however, examined and published a large number and has, I believe, examined many more since.[7] Whereas in Case 4 the clinical picture is indistinguishable from that of typical fibroma, the microscope reveals the fact that the growth is of epithelial and not connective origin. This contradiction is not uncommon. Of the other two, it is probable that only Case 1 can be considered a true fibroma, Case 3 being a product of inflammatory and mechanical irritation. The three well-recognised predisposing factors in the origin of laryngeal growths are present in Cases 3 and 4—namely, nasal obstruction or disease, laryngitis, and over-use of the voice. If Cases 2 and 3 be compared as regards their etiology and site, it would appear that they differ chiefly in degree, for owing to the laryngitis in Case 3 the mucous membrane covering the cords was soft and swollen, a condition unfavourable to the formation of a "hard corn." The friction, however, with the opposite cord resulted in the irritation and clotting in the congested vessels of the submucous tissue, which in turn stimulated growth in its immediate vicinity. The occurrence of such a growth therefore is no mere accident, but a direct result of the occupation of the patient. No such sequence of events can be suggested as the origin of the growth in Cases 1 and 4, but it is probable that in Case 4 the patient had been using "unwisely and too well" her voice, before the complete subsidence of one of her attacks of laryngitis, resulting in some endo- or extra-vascular clotting, which was the original irritating source of the growth.

In conclusion, it may be said that efficient nasal breathing and the correct use of the voice will prevent the occurrence of such growths in those predisposed; and should such growths occur the methods I have advocated for their removal would greatly minimise the risks of damaging the vocal cord and thus the best results be expected.

Wimpole-street, W.

THE INFANT IN THE SCHOOL MEDICAL EXAMINATION.

BY A. D. EDWARDS, M.B., B.S. LOND., B.SC., D.P.H., L.R.C.S. EDIN., L.F.P.S. GLASG., &C.,
DEPUTY MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER TO THE COUNTY BOROUGH OF NEWPORT, MON.

THE examination of the infant of four or five years of age forms a large part of the work of the school medical officer and as this class is, on account of the tender years of children, the most difficult to deal with, it is necessary that the examination should be conducted warily and with the least possible disturbance to the child. It is not sufficient that the examining medical officer should exhibit in a general way the characteristics of tact and kindness; for if one timid infant returns to its class frightened and tearful after the medical examination it is certain that many, if not most, of the other children from that class will come to the examining room with a predisposition to cry and to be frightened, and there will then be an increased possibility of a large number of examinations being carried out under the most disadvantageous circumstance—that of a frightened, crying child.

Fear of the unknown is well marked in all children, and in the infant class with which we are dealing it is probably the most powerful instinct next to that of mother-love. Only a few months before the medical examination these children of four or five years of age have made their first venture out of the home circle into the daily school life, and their instinctive fear of the unknown and of the unusual is often increased by certain attendant circumstances. Under most education authorities a notice is sent to the parents inviting one of them to attend at the medical examination of the child, and a frequent result of this is that the child hears the subject discussed at home and obtains an erroneous impression of the matter to which its own faculty of imagination contributes largely. Another result of this notification is that on the morning of the examination the child often receives an unusually thorough washing and scrubbing and is then arrayed in clothes which are donned only on Sundays and special occasions. The unusually vigorous ablution and the wearing of Sabbath apparel mark out the day as being special; from the home conversation the child has gathered that it is not a picnic or other pleasure-giving day, and by the time it arrives at school an excitable child will be in a state of nervous tension, which, if its feelings are not carefully studied during the examination, will surely end in fright and tears and thus render the examination a matter of extreme difficulty; and the return of such a child to its class will result in much trouble in the examination of children immediately following. So that although with ordinary care a number of normal infants of four or five years of age may be examined successfully without one of them crying or being frightened, it is most important that the examination should be conducted in such a way that even a nervous or timid child should be put at ease, and indeed it should be the object of the examining medical officer to make the child interested in the examination—an object which, if suitable means are employed, is neither impossible nor difficult.

With the object of making a good start it is well that when the infant enters the examining room there should not be more than two or three adults present. It is neither necessary nor wise to have in the room any adult besides the medical officer, the school nurse, and the head teacher. If the latter is an efficient administratrix she will be well known to the child, who will look upon her as a friend, but it will be found that the presence of the child's mother more often hinders than aids the examination, and in most cases a timid child will respond more readily to tact and kindness from the medical officer in the absence of the mother—a fact which is explained by the instinct of the child to run to its mother in the presence of strangers.

Important information concerning the child's previous illnesses, general health, &c., can be obtained at a preliminary interview with the mother, and in this connexion it may be noted that an opinion of the child's mental capacity, should be obtained not only from the head teacher but also from the governess who has most to do with the child. In the case of a very timid child, the presence of another child from the same class, preferably one who has been examined and has "made friends" with the medical officer, is an advantage, but it is inadvisable to keep one child waiting its turn and watching the examination of another.

The order of the examination is important. Thus the weighing and measuring should not be done first, for an infant is apt to become uneasy if made to stand on the scales immediately after entering the room, so that the proceeding should be left until the child's interest and confidence have been gained; nor should the mouth and throat be examined until the end. Two things should be avoided during the examination—fussiness and sudden and rapid movements. The confidence of a nervous infant may be won by gentle attention, but to be fussed over by two or three adults at the same time is to the liking of no child.

The distrust of jerky and sudden movements which is displayed by infants of four or five years is the same instinct which is described by Richard Jefferies as existing in wild animals, and gentleness in voice and gesture should be therefore the habit of every school medical officer. Although toys are useful in estimating the mental capacity of the infant their routine use during the examination is not to be recommended, for the interest of the child should be centred in the medical officer and in what he says rather than in an external object; and, moreover, although the toys may help to put a child at ease and to prevent fright during the examination, they may be so attractive that the parting with them at the end of the examination will result in a flood of tears. The examination of the child should begin as soon as it enters the room, for the faculty of keen observation should be developed so as to give the fullest information concerning the child, and the general appearance, gait, and pose of the head may be observed at a glance, and the presence of the adenoid facies, rickets, or deformities should also be noticed. Before the examination of the chest is proceeded with the child should be spoken to and encouraged to speak and to become used to the stethoscope which, with a little suggestion, may be regarded as a new kind of toy. Not a few children are inclined to look upon the stethoscope with distrust, but their aversion may be very readily overcome by asking them to hold the chest-piece to the ear in order to "hear the bird sing," and whilst the piece is held to the ear a sibilant whistle may be produced, the tip of the tongue being placed behind the upper incisor teeth, approximating to its position in the act of hissing. The lips should not be used in the production of this sound, which is the best test of a child's hearing, and with a little experience the intensity can be varied so that a standard for normal hearing can be obtained. The fact that the little bird is heard to whistle must be ascertained not by questioning but by observing the child's face, for the resulting smile is not only almost invariable but is the most valuable affirmation to be obtained. During this performance, which need not take more than 30 seconds, the school nurse should be loosening the infant's clothing, and the child should by this time be interested enough to place the stethoscope on its chest when asked to do so, and it will be an advantage to allow the little hand to remain on the end of the stethoscope whilst it is moved to different parts of the chest.

[7] Wyatt Wingrave: Journal of Laryngology, Rhinology, and Otology, vol. xxi., p. 5.

The weighing and measuring of the child may now be undertaken; after which the manual examination for the submaxillary and cervical glands should be done. For this the child must bend the head downwards in order to relax the cervical muscles, and this opportunity is favourable for the inspection of the condition of the scalp and head at the crown; in the same way the sides of the head may be inspected whilst the examination for external ear disease is proceeding. The infant is less likely to be frightened by this part of the examination, but it is well to retain the child's interest by talking; and, indeed, it is a golden rule that throughout the examination the child should not be too conscious of the fact that it is being examined. The examination of the mouth and throat is left until late because it disturbs the child most, and in this connexion the shape and material of the spatula are not unimportant. Vulcanite is to be preferred to metal, the coldness of which makes it uncomfortable for the child; when the instrument is disinfected by means of biniodide or other compound of mercury, metal of course cannot be used. Here also reference may be made to the question of the advisability of giving sweets to the child. It is true that the school medical officer should rely on his tact and manner to win for him the infant's confidence, but there are not a few cases in which the appeal to "cupboard love" is necessary, and in which the giving of a small sweet will make the difference between an examination of a crying, struggling child and one which is done quietly, pleasantly, and successfully. Particularly useful is the giving of a sweet in the examination of the mouth and throat, for however reluctant the little one is to allow its mouth and throat to be examined, it will almost invariably allow the doctor to "see if the sweet is finished," and the whole process of the examination will be regarded as part of a game, and even the last slight pressure of the spatula on the tongue which is necessary to reveal the tonsils will not interfere with the smile which comes when the examination is finished.

Thus it will be seen that by methods which the above remarks indicate in a cursory manner the infant may be not only interested in the examination but may be made to enter into it as a game; and such methods will be found to be particularly useful in the case of timid and nervous infants who, if frightened, would be found to be difficult and even impossible to examine fully without physical force. Too much attention should not be paid to quiet crying in an infant, and it has at least one advantage that the occasional long-drawn inspiration gives one a good opportunity of listening to the lung sounds. But even gentle crying should be a rare occurrence, and by tact and kindness and the use of suitable methods the confidence of the most timid infants of four and five years may be won by the true lover of children.

Newport, Mon.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF SEPTIC PLEURISY AND PERICARDITIS RUNNING AN AFEBRILE COURSE; DEATH WITHIN SIX DAYS OF ONSET OF SYMPTOMS.

BY C. W. WINDSOR, M.A., M.D. CANTAB.

THE patient was a thoroughly healthy man, aged 40 years, living in a country village, occupying himself with farming for a living and shooting for sport. The only previous illness of consequence was a severe attack of pleurisy 16 years ago; but ten weeks before the onset of the illness to be described below he had a very sharp attack of shingles which pulled him down somewhat. On each of the three days before the beginning of the fatal illness he had been out shooting, and beyond being a little fagged was in apparently good health. On Sept. 28th at tea he complained of his throat being stiff and full but did not make much fuss about it. This condition became much worse during the night, so that a medical man was sent for early next morning, when the uvula was found to be much swollen, almost blocking the fauces and interfering considerably with breathing. His temperature was 99° F. Later in the day this œdematous swelling was freely scarified, to the patient's relief; his temperature rose in the evening to 102°. Next morning, Sept. 30th, the swelling of the uvula and soft palate had subsided but the patient looked ill with rather a cyanosed complexion; his temperature was 101°, his breathing was quick and shallow, his voice had almost gone, and swallowing was difficult, the symptoms pointing to some œdema of the glottis; the pulse was rapid. During the night he complained of very severe pain in the upper part of the abdomen, especially over the liver. On examination of the chest friction sounds were heard over the lower part of the right lung, the axilla, and also at the left base behind; while over the cardiac area there were abundant soft crepitations but no pericardial friction. There was no expectoration. The temperature was 99°, the respirations were 40, and the pulse was 120. The heart sounds were clear. The urine and abdominal viscera were normal. The uvula and mouth were healthy. The skin was perspiring freely. The feet were cold. There was cyanosis of the face. This condition of things quickly developed into well-marked pleurisy at each base, with some consolidation of the underlying lung tissue. Expectoration was slightly rusty coloured. The temperature remained normal but the pulse-rate varied between 140 and 160 and respirations were from 40 to 50. There was a constant desire to sit up in a chair, as he could not rest in bed. The face was a bad colour and the patient was greatly exhausted and suffered from sleeplessness. His mind was quite clear. In this condition the patient was seen in consultation by Dr. Laurence Humphry. Without development of further physical signs the condition became rapidly worse and the patient died on Oct. 5th after six days' illness.

Nothing special beyond pneumococci was found on bacteriological examination of sputum. Treatment was on ordinary lines with a view to promote sleep, to relieve pain, and to maintain strength. Antistreptococcic serum was injected, oxygen and hypodermics of strychnine were freely used. At the post-mortem examination there was very intense pleurisy on each side with membrane a quarter of an inch on both surfaces of the pleura, also consolidation of the lung in each lower lobe. The whole pericardium was lined with a similar thick membrane, showing a reticulated surface and resembling uncooked tripe. There was some congestion of the larynx. There was considerable enlargement of the spleen. Cultivation growths from the affected viscera showed staphylococci and streptococci, pneumococci, and also a large bacillus resembling bacillus anthracis but which proved to be a putrefactive organism. The interest of this case lies more in the speculation as to its origin than in the actual lesions. The œdematous swelling of the uvula and soft palate was attributed to the sting of a wasp or other insect, possibly occurring while taking tea, at which the patient ate some strawberry jam. The patient, however, disclaimed any knowledge of having been stung or bitten. There had been no exposure to cold or wet. The bad prognosis given was based upon the afrebile course of the illness, the extremely rapid pulse, the cyanosis and cold sweats with rapid exhaustion. The case was apparently one of septic infection resulting from some cause unknown, unless the hypothetical sting be looked upon as the point of entrance of some infective organism. Inquiry was made as to the possibility of infection from any diseased animals or farm stock with a negative result.

Royston, Herts.

INDUCTION OF LABOUR *V.* MORPHINE IN ECLAMPSIA.

BY W. BOXER MAYNE, M.R.C.S. ENG., L.R.C.P. LOND.

THE following is a report on a severe case of eclampsia showing the relative value of hypodermic injections of morphine and induction of labour as treatment.

I was called about 7 A.M. to see a young woman whose husband informed me that she was eight months pregnant and that she had just had a fit. On arrival at the house I found that the patient, a primipara, 20 years of age, had had in the meantime a second fit, the first having occurred about 6 A.M. and the second about 7 A.M. On inquiry I found further that she had complained for a day or two of violent headache and also of pains in the back. She was very puffed about the face, her feet and ankles being very œdematous. Though strange and excitable in her manner she nevertheless allowed, after a little persuasion, a vaginal examination; the os was of about the size of a shilling and the vertex was presenting. Having found morphine a great success in other cases I resolved to give the same treatment further trial and, as before, to commence with a hypodermic injection of half a grain. Whilst getting the injection ready the patient had a third severe fit. In addition to the morphine I placed two minims of croton oil with a little butter on her tongue and had her wrapped in a hot pack. At 10 A.M. she had a fourth fit, a nurse in attendance administering, by my instruction, a further hypodermic injection of a quarter of a grain of morphine, which was repeated by myself about 12.30 A.M., the patient being then in a semi-conscious state. I had no sooner gone than the patient had a fifth fit; and at 3 P.M. a sixth, when the nurse gave her a third hypodermic injection of a quarter of a grain of morphine. Seeing the patient again at 4.30 and finding that she had had the two fits since my previous visit and that she was in a comatose condition, I determined to postpone no longer the last resource, viz., induction of labour. Administering chloroform, I managed to dilate the os sufficiently to enable me to perform version; accelerating matters by traction I presently delivered a living child. As a precaution I gave a hypodermic injection of four tabloids of ergotinine citrate, each 1-200th grain, and one of strychnine, 1-30th grain. From this time nothing untoward occurred; the patient spent a quiet night and was able to recognise me the following morning, though still dazed and heavy. During the day she passed a little urine with her motions, and the day following, under the influence of diuretics, &c., a fair amount; this, the first I had been able to examine, presented about one-third albumin. The progress of the patient since has been uninterrupted.

Swindon.

A CASE OF PLASTIC RESECTION OF THE BREAST AND ITS BEARING ON THE ROUTINE PRELIMINARY INCISION OF BREAST TUMOURS.

BY C. HAMILTON WHITEFORD, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient, aged 24 years, married, one child 19 months old, was operated upon on Nov. 10th, 1907, and was shown at a meeting of the Plymouth Medical Society on Feb. 19th last. For the past four months she had noticed in the centre of the upper and inner quadrant of the left breast a tender thickened area of the size of half-a-crown. This tender area, after treatment by local applications for four months, was still a source of discomfort to the patient who, having to be anæsthetised for operation on an anal fistula, decided to have the breast dealt with at the same time. The breast was treated by Collins-Warren's modification of Thomas's operation. The skin incision, nine inches in length, exposing the fibres of the greater pectoral muscle, commenced in the nipple line in the fold below the breast, was prolonged upwards along the lower and outer margin of the breast and was further extended along the under surface of the anterior axillary fold. The breast was then dissected upwards and inwards off the greater pectoral muscle until the deep surface of the upper and inner quadrant was exposed. The mass was incised on its deep surface and the diagnosis of chronic mastitis was confirmed. The segment of breast tissue containing the tumour was excised. This wedge-shaped area included the whole thickness of the breast, but stopped short at the subcutaneous fat, which was not disturbed. The base of the wedge measured three inches; the apex of the wedge was situated one inch above and one inch to the inner side of the nipple. The breast was reconstructed by closing the wedge-shaped gap and fixed in its normal position. This was done by four layers of catgut sutures. The first layer, including the subcutaneous fat, approximated the superficial portions of divided breast tissue. The second layer approximated the deep portions of cut breast surface. The third layer, the breast having been turned down into its natural position, attached the breast to the edge of the greater pectoral muscle. The fourth layer approximated the connective tissue immediately beneath the skin incision, which was sutured as advised by Warren without drainage. In spite of many ligatures and firm pressure by dressings a hæmatoma developed between the breast and the greater pectoral muscle. This hæmatoma became infected and was drained through the skin incision.

When seen four months after the operation the breast was in its natural position, the skin over the resected area was normal, showed no depression, with only a suspicion of flattening, and admitted of the wearing of a low evening dress. It is interesting to note that this satisfactory result ensued in spite of the unfortunate incident of the hæmatoma. The long skin incision and freeing of the breast by cutting off the nerve-supply rendered the lower portion of the breast at first almost completely anæsthetic. At the present time this anæsthesia has nearly disappeared. In view of the extensive area involved in the dissection it is probably safer to drain for 24 hours the retro-mammary tissues by a tube passed from the lowest part of the skin incision to the deep surface of the sutured breast area.

The above method has an important bearing on the best position for the preliminary incision, which should be made into every breast tumour as a preliminary to radical treatment. The surgeon who, in performing a radical operation for supposed malignant disease of the breast, neglects the elementary precaution of incising the tumour, as a means of either confirming or disproving the diagnosis, runs the risk of finding himself in the unenviable position of having performed Halsted's, or some equally extensive operation, for a simple tumour such as an adenoma or abscess. An incision made into the tumour directly through the overlying skin in the event of the tumour proving non-malignant and needing only local removal, results to a certainty in a scar and probably in a depression. This scar, or scar plus depression, if situated in the upper half of the breast, interferes with the wearing of a low-necked dress. By employing Warren's skin incision, followed by incision of the tumour on its deep surface, such disfigurement can be avoided. If the tumour is found to be innocent it can be treated as in the case recorded above. If the tumour proves to be malignant, in order to minimise risk of dissemination of cancer cells its cut surface is cauterised and a pad of gauze is packed between the breast and the greater pectoral muscle. The breast is turned outwards and downwards so as to occupy its normal position and is fixed to the greater pectoral muscle by a continuous suture. After discarding all instruments, gloves, &c., used for the exploratory incision, a fresh supply is employed in the performance of the radical operation.

Adoption of the above method (which, while not unknown, is certainly not in general use) as a routine preliminary to operations on mammary tumours situated in the upper half of the breast will, in the case of an innocent tumour, prevent a disfigurement which, to a sensitive patient, is distressing and surgically is unnecessary.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Ovarian Pregnancy Co-existing with Intra-uterine Pregnancy.—Exhibition of Specimen.

A MEETING of this section was held on June 11th, Dr. HERBERT R. SPENCER, the President, being in the chair.

Dr. J. M. MUNRO KERR read a paper on a case of Ovarian Pregnancy Co-existing with Intra-uterine Pregnancy. The ovary containing the ovarian pregnancy was removed by operation. The embryo was at a stage closely corresponding to one described by Graf von Spee. It was so much injured, however, that reconstruction was not possible and the sections were exhibited, the ovum being the youngest yet recorded in that position, to demonstrate the nature of imbedding in the ovary. There was a large corpus luteum, the contour of which was intact, except at one point where there was young organising connective tissue, forming a continuous strand reaching from the centre of the corpus luteum to the margin of the implantation cavity. The cavity had been excavated in the ovarian stroma, and its walls were formed in part of connective tissue in a state of coagulation necrosis, but to a greater extent by fibrin and blood clot. The surface of the ovary had been ruptured and the ovum was evidently in the process of extrusion. There were absolutely no signs of any formation akin to decidua and the more actively destructive phases demonstrated in the first specimen had obviously persisted until a considerable part of the ovary had been destroyed. The ovum lay more or less free in the implantation cavity; the villi were irregular and many were overtaken by degenerative changes but they contained blood-vessels and showed precisely the same coverings as in a uterine ovum at the same stage of development. The sections prove: 1. That the ovum can be imbedded in the ovarian stroma outside the Graafian follicle. 2. That it imbeds itself just as does the ovum in the uterus in connective tissue rich in blood-vessels. 3. As has already been shown by C. von Tussenbroeck and others, the uterine epithelium is not necessary for plasmodial formation; as this ovum lies in the ovarian stroma neither can the plasmodium be derived from the follicular epithelium. The two cases combined once again demonstrate the nature of implantation. The process involved is essentially a destructive one; the primary necessity for the ovum is a nidus of connective tissue rich in blood-vessels. Formation of decidua is not essential; it is a defensive reaction against the destructive activities of the trophoblast, which it limits and controls.

Dr. JOHN H. TEACHER gave lantern and microscopic demonstration of an extremely young human ovum (Teacher-Bryce ovum). This specimen represents the earliest stage of the human ovum which has been found and presents features hitherto unknown. The ovum was found by Dr. Teacher in a portion of decidua shed by abortion. It is imbedded in the decidua in an oval cavity filled with maternal blood and having a small orifice closed by a fibrinous plug. The walls of the blastocyst (which measures internally 0·77 by 0·63 by 0·50 millimetre) are composed of a thin cellular layer and a very irregular plasmodial formation together constituting the trophoblast. Within this there is a delicate mesoderm, towards the centre of which lies an extremely small embryonic rudiment. The ovum, although imbedded, is not yet attached to the decidua. An unusually clear history has been obtained, which appears to afford a fresh starting point for the estimation of the age of young ova in general. The age of the present ovum is estimated at from 13 to 14 days from fertilisation.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

Demonstration of Experiments.

A MEETING of this section was held on June 27th, on the invitation of Professor A. R. Cushny, in the Pharmacological Laboratory of University College, London, Dr. T. E. BURTON BROWN, the President, being in the chair.

Professor CUSHNY showed some most interesting experiments demonstrating graphically the effect produced on a dog's heart (the animal being in a condition of complete anæsthesia) by the administration of certain drugs such as chloroform, when the heart's action weakened, ether, and pilocarpine.

The museum of the College was visited and the valuable exhibition of Egyptian antiquities collected by Professor Flinders Petrie was viewed.

Reviews and Notices of Books.

Gynecology and Abdominal Surgery. Edited by HOWARD A. KELLY, M.D., F.R.C.S. Edin. (Hon.), Professor of Gynæcologic Surgery at the Johns Hopkins University; and CHARLES P. NOBLE, M.D., Clinical Professor of Gynæcology at the Women's Medical College, Philadelphia. Illustrated by HERMAN BECKER, MAX BRÖDEL, and others. London and Philadelphia: W. B. Saunders Company. 1907. Vol. I. Pp. 851.

IN the preface to this work the editors point out that the great advances made in gynæcology have constituted the very backbone of the abdominal surgery of to-day, and that *pari passu* with the labours of the gynæcologists have gone the developments of the abdominal surgery of the abdomen as a whole. That the operating gynæcologist should have had a thorough training in general surgery is an essential which is liable to be overlooked by some writers, and the likelihood of an abdominal operation, even when undertaken apparently for the simplest gynæcological affection, calling for the exercise of the highest skill of the general surgeon is no small one. The present work, therefore, seems to us to be of value in the stress which it lays on the close relationship between general abdominal surgery and gynæcology.

The first chapter on gynæcological technique is written by Professor Howard Kelly and contains a complete account of the various methods of sterilisation. The scientific basis of gynæcology is set forth in two chapters concerned with the bacteriology and pathology of the diseases of women. This arrangement leads to a certain amount of repetition, but as regards the pathological anatomy of the various affections this is more than compensated for by the excellence of the chapter on pathology which is contributed by Dr. Elizabeth Hurdon.

In the chapter devoted to medical gynæcology, by Dr. Charles P. Noble and Dr. Brooke M. Anspach, such conditions as disorders of menstruation, inflammatory affections and infections of the pelvic organs, and displacements of the uterus are considered, as well as the various neuroses which may be met with in gynæcological patients.

The next chapter is headed Non-plastic Operations on the Vulva and Vagina, and is written by Dr. Anna M. Fullerton. In this are included such different processes as inflammatory diseases, ulcerative processes, hypertrophy, and atrophy of tissues and new growths. The important subjects of plastic operations on the perineum, vagina, and vulva are fully discussed in the next chapter by Dr. Noble who deals with them at considerable length. He prefers Emmet's operation in the treatment of cases of relaxed vaginal outlet and thinks that it is better than Tait's flap-splitting operation, because the latter does not afford any satisfactory means of disposing of a rectocele and of securing union of the torn or separated fibres of the levator ani muscle. In the treatment of cases of chronic inversion of the uterus discission of the cervix, followed if necessary by incision of the body of the uterus from below upwards, is preferred to Küstner's operation.

The section on the diseases of the bladder and urethra, by

Dr. Guy L. Hunner, contains a very good account of cystoscopy as practised with Kelly's cystoscope. The author gives several useful hints in the manipulation of this instrument which should prove of service to the beginner. In the treatment of cases of tuberculous disease of the bladder the method suggested by Casper of using solutions of perchloride of mercury in place of silver nitrate is approved of. In the closure of simple vesico-vaginal fistulæ Dr. Hunner uses no anæsthetic beyond a hypodermic injection of morphine. In discussing the surgical treatment of vesico-vaginal fistulæ Professor Kelly points out that the best proof of the progress made in the last 40 years in the treatment of these distressing cases is the fact that the operation of colpocleisis is practically never performed at the present day. Some interesting examples of ingenuity displayed in the restoration of the destroyed urethra are given by the author and Dr. Noble and they are good illustrations of what can be done even in apparently the most unfavourable cases.

For the young surgeon the preparation and after-treatment of his cœliotomy cases is always a matter of much importance and the excellent chapters contributed by Dr. Noble on these subjects will repay perusal. How thoroughly the book has been compiled is illustrated by the fact that a special chapter on the methods of closure of the abdominal wound is contributed by the same author. Dr. Noble favours suture of the layers of the abdominal wall separately and uses for this purpose cumol catgut. He claims that this method minimises the risk both of suppuration of the wound and of the occurrence of post-operative hernia. In the treatment of cases of retro-displacements of the uterus he reports very favourably of the Alexander-Adams operation. In some 200 instances of this procedure he has seen no herniæ following the operation, and the only complication noticed during pregnancy was some complaint of tugging in the groins caused by the traction of the enlarging uterus upon the shortened ligaments.

Dr. Alexander J. C. Skene writes on ovariotomy and in the list of contraindications which is given by him we note extreme flatulent distension of the bowels; this hardly appears to us an adequate reason for not removing an ovarian cyst when it is present. The opinion expressed by Dr. Henry T. Byford that posterior colpotomy is usually preferable to anterior colpotomy in carrying out vaginal section for diseased ovaries and tubes is not that held by most operators. As Wertheim points out in his book on vagino-peritoneal operations in the operative treatment of the normal pelvic organs the anterior route is always preferable, and in the majority of pathological conditions it is to be preferred to the posterior. Dr. Byford agrees, however, with Wertheim in recommending that the fundus uteri should not be delivered into the vagina but only the adnexæ. Dr. Clarence Webster gives an excellent account of the various operations which may be performed for removal of the uterine appendages. The important question as to whether the uterus should be removed as well as the appendages in cases in which the latter require extirpation is examined critically by Dr. J. M. Baldy. He is unreservedly in favour of the hysterectomy, and maintains that the removal of the uterus not only lessens the mortality of the operation but also renders the convalescence smoother, easier, and more satisfactory. In 223 cases which he has collected the death-rate was only 2·68 per cent. The numerous advantages of treating cases of pelvic abscesses by vaginal incision and drainage are becoming more and more appreciated by gynæcologists at the present time, and Dr. Noble has shown that there is a mortality of some 27 per cent. in cases treated by the abdominal route as contrasted with a mortality of only about 2 per cent. in patients treated by vaginal incision and drainage.

Two chapters on the operative treatment of fibroid tumours are contributed by Dr. Noble. He is so well known as an authority on this particular branch of gynæcology that we need not say that these chapters contain all that there is to be said on this subject. Dr. Noble is of opinion that the chance of cancer developing in the cervix is so small that he prefers to leave it and to perform whenever possible a supravaginal amputation of the body of the uterus. He is in favour of myomectomy in suitable instances and has performed abdominal myomectomy himself in some 8 per cent. of his cases. These figures are in marked contrast to those of Professor Kelly who has done 306 abdominal myomectomies and 691 hysteromyomectomies. A table is given showing the results of 643 hysteromyomectomies and abdominal myomectomies with a mortality of 13 or 2 per cent., a figure which, of course, only shows the danger of these operations in the hands of the best surgeons, for, as Dr. Noble points out, these figures by no means represent the mortality of these operations when performed by inexperienced and untrained surgeons.

Undoubtedly the most important question at the present time in gynæcology is that relating to the operative treatment of cancer of the cervix uteri. In a chapter entitled "Radical Abdominal Hysterectomy for Cancer of the Uterus," Dr. John G. Clark discusses the whole question very fully. He is unreservedly in favour of the radical abdominal operation and recommends it in all suitable cases. In interesting contrast to this chapter is the next one in which the Byrne method of treating carcinoma of the uterus is described by Dr. Werder. It is appropriate that in such a volume as the present written by American surgeons the important work accomplished by Byrne should be duly recognised. The principle which he so earnestly advocated—namely, that all incisions in the extirpation of cancerous tumours should be made by the cautery knife—is one which is now followed by many surgeons and is without doubt a procedure of great importance. When we read this account and realise how good were both the immediate and also the remote results of his operations it is surprising to think how few gynæcologists know anything of his work or are ready to give him the great credit which he deserves. There can be no question that early cases of carcinoma of the cervix are better treated by Byrne's method than by any other, inappropriate as it must be to more extensive growths, although even here the principle of always using the cautery in place of the scissors or knife still holds good. Dr. Werder describes an excellent modification of Byrne's operation designed to suit the needs of modern surgery. The remaining chapters are on Vaginal Hysterectomy, from the pen of Dr. Fernand Henrotin, and a chapter on the Conservative Treatment of the Tubes and Ovaries by Professor Kelly who in conjunction with Dr. Elizabeth Hurdon has written the final chapter in this volume on Operations before Puberty.

The book contains a great deal of information and is beautifully illustrated, the drawings being mainly the work of the well-known artists Herman Becker and Max Brödel. The whole is a most valuable addition to gynæcological literature and forms a striking testimony to the good work being done by the American school of gynæcologists.

The Diagnosis and Treatment of Pulmonary Tuberculosis. By FRANCIS M. POTTENGER, A.M., M.D., Medical Director of the Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, California; Professor of Clinical Medicine, Medical Department, University of Southern California. London: Baillière, Tindall, and Cox. 1908. Pp. 377. Price 15*s.*

IN the introductory remarks to this work the author says: "As yet, however, no book has appeared which endeavours to give a full discussion of the diagnosis, both early and late, of tuberculosis, nor has any of them considered the treatment of tuberculosis in the light of modern studies in immunity." This statement is too sweeping. Many books have appeared in this and other countries containing chapters or sections dealing fully with the diagnosis of pulmonary tuberculosis, and the treatment of the disease by tuberculin and other allied preparations has received careful attention. Very wisely no one method of treatment has yet obtained general acceptance, thus indicating that therapeutic measures based on the theory of immunity are still on their trial. The advances which have already been made since Dr. Pottenger completed the writing of this book will necessitate material alterations in any future edition, especially in regard to auto-inoculation, as illustrated by the employment of regulated manual labour in connexion with ordinary "sanatorium" methods.

In the first chapter some observations are made upon the facts that tuberculosis often remains unrecognised and that the disease may undergo spontaneous cure. These facts are proved by experience in the post-mortem room, but there may be a tendency to err in the opposite direction and to make a diagnosis of tuberculosis when such a condition is not present. For instance, Dr. Pottenger remarks: "There is no question but that neurasthenia in young girls is often due to a tuberculous deposit in the lung." We doubt whether clinical experience would substantiate this. In some cases of early tubercle neurotic symptoms may be prominent but it is questionable whether the connexion between the two is so common as the author suggests. We agree with his views as to the "picture of tuberculosis," as he terms it—namely, that it is a localised infection which every now and then shows a tendency to spread to new tissue, especially to that surrounding the parts affected. With the infection of new tissue symptoms either slight or severe, may be produced according to the area involved, the toxins produced, and the susceptibility of the individual. As Dr. Pottenger aptly expresses it: "The picture is that of a series of quiescences and activities."

A good description is given of the signs and symptoms of early pulmonary tuberculosis and it is rightly suggested that they must be carefully considered and their proper importance conceded to them before a diagnosis is arrived at; for it is self-evident that one or even several of them may be present and yet the patient may be not suffering from tuberculosis. Nor is it enough to know that a tuberculous process is present; it is equally important to know whether such a process is active or quiescent. In the portion of the work devoted to the question of diagnosis all the necessary points to be observed are carefully described and discussed.

Dr. Pottenger gives a full description of the stethoscope which he employs. The chest-piece differs from any of those which we have hitherto seen. It is made of hard rubber and has two chambers, one in the centre with which the ear-pieces are connected and an outside one connected with a rubber bulb. By pressing the air out of the bulb a partial vacuum is formed in the outer chamber, so that when it is pressed on the chest wall it is held by the suction caused by the attempt of the bulb to expand. The outer chamber is said to act as a barrier to extraneous sounds and its suction action to afford exact conditions for comparison at different examinations, by avoiding differences of pressure on the chest.

The consideration of the various forms of treatment of pulmonary tuberculosis is full and detailed. A moderate tone prevails throughout; the anticipation of results is neither too optimistic nor too pessimistic. The remarks on diet, too, are sound and reasonable, and due caution is enjoined with regard to over-feeding. The question as to what is meant by "cure" is discussed, and the author maintains that the only trustworthy test as to whether or not the patient is cured is the tuberculin test.

We have perused this work with interest, and although there are some points upon which we cannot agree with the author, we consider that the book as a whole contains valuable information and advice.

An Elementary Course of Zoology. By W. N. PARKER and the late T. JEFFERY PARKER. Second edition. London: Macmillan and Co. 1908. Pp. 624. Price 10*s.* 6*d.* net.

THE second edition of this now well-known guide to practical zoology differs in only a few points from the first. Monocystis has been added as an example of the Sporozoa, while the student is guarded against forming too narrow a conception of the annulate worms by an account of the marine form Nereis being appended to the description of the common earthworm. In addition to this Obelia has been chosen in place of Bourgainvillea to follow Hydra as an example of the hydroid polypes. All teachers of biology and very many students know the book and to them no commendation is necessary. Those students who do not know it we would strongly advise to look at it before deciding on a laboratory manual, because, in our opinion, it is the very thing which a student wants. It is written by two men with a long experience of the needs and difficulties of students as well as with a real knowledge and love of their subject, while the clear and simply worded descriptions always lead up to some important generalisation which a student of average capacity generally grasps before it is definitely enunciated.

From the point of view of the teacher of biology in a medical school the ever present danger is that biology may become a "cram" subject instead of an intellectual training. The facts themselves to a medical man are perhaps trivial but the training derived from observing those facts and deducing general laws from them is of the highest value and makes the future teaching of anatomy and physiology far more easy and pleasant alike to the teacher and the taught. We believe that students seldom read the introductions to books, but we wish that they would make an exception in the case of this one and realise that biology, although it unfortunately has to be taught solely in a laboratory and has a dreaded examination as its apparent goal, is nothing more than the systematised continuation of those observations on the habits and external appearances of animals and plants which every healthy-minded boy has made and has taken pleasure in making.

The plan of the work remains as before. More than a third of it is devoted to the frog which is used as the type of a vertebrate animal and serves as a peg on which to hang the main facts of vertebrate morphology and physiology. Then follow the various types of animals, beginning with amœba and ending with the rabbit. The working directions are so clear that, given the actual types, a student could master the subject without a teacher if no teacher were to be had. Without practical work, however, as the authors more than hint, biology were better left alone.

Shaw's Manual of the Vaccination Law, containing the Vaccination Acts, 1867, 1871, 1874, 1898, and 1907; the Vaccination Orders, 1898, 1899, 1905, and 1907; and the Instructional Circulars and Memoranda issued by the Local Government Board. With Introduction, Notes, and Index by JOHN LITHIBY, C.B., LL.B. of the Middle Temple, Barrister-at-Law. Eighth edition. London: Butterworth and Co.; Shaw and Sons. 1908. Pp. 285 + 31.

VACCINATION and the legal obligation to submit children to it may not afford a vast field to the lawyer but they have certainly given the opportunity for fierce forensic struggles.

These have not always been confined to the police courts, but on the whole the law of vaccination intimately concerns the ordinary citizen and still more so the members of the profession whose duty it is to carry it into effect. These may at any time desire to satisfy themselves as to their position and should welcome the appearance of a fresh edition of so well edited a handbook as "Shaw's Manual." This is its eighth issue, and comparing it with a previous one, the sixth, published in 1898, we find that a decade of legislation has added nearly 100 pages to a small octavo volume. The manual, in addition to Acts, departmental orders, and notes strictly confined to the law of its subject, contains a tersely written and instructive introduction dealing with the history and progressive stages of compulsory vaccination, which can be read with interest by those not desirous of studying sections and clauses with their interpretations in the courts in detail. Ten years ago a new statute had created, or was in course of creating, the "conscientious objector" and the editor then wrote in the spirit of prophesy that whether its operation would be for good or for evil could not with certainty be predicted but that it was not to be looked upon as a final settlement of the vaccination question. He also quoted from the *Times* of August, 1898, an extract from Lord Salisbury's speech in the House of Lords on the subject of the Bill, which may now be read in the light of subsequent events with respect for that statesman's insight and sound sense. The editor writes now: "It has been alleged by many that the change in the method of obtaining exemption will probably diminish the number of children vaccinated. If, however, the Act is followed by results similar to those which attended the exemption clause in the Act of 1898 the number of children vaccinated will be increased rather than diminished." It is not always easy to distinguish between that which is *post hoc* and that which is *propter hoc*, but it is to be hoped that in a future edition of his work Mr. Lithiby will be able to point to the fulfilment of a prediction which he evidently intends. The absence of grounds for seeking and claiming public martyrdom, combined with the spread of intelligent appreciation of the protective measures surrounding modern vaccination, should do much to further such a consequence of the Act of 1907, and also, we may add, to postpone such further legislative changes as would render the present edition of "Shaw's Manual" obsolete. For some years at all events it should prove an efficient guide to those desirous of carrying out smoothly the law as it stands.

LIBRARY TABLE.

Diseases of Children for Nurses, including Infant Feeding, Therapeutic Measures Employed in Childhood, Treatment for Emergencies, Prophylaxis, Hygiene, and Nursing. By ROBERT S. MCCOMBS, M.D., Assistant Physician to the Dispensary and Instructor of Nurses at the Children's Hospital of Philadelphia, &c. Illustrated. London and Philadelphia: W. B. Saunders Co. 1907. Pp. 431. Price 10*s.* net.—On looking through this book we are compelled to ask the question, What can be the author's idea of the functions of a nurse? In this old-fashioned country there is, we think, an idea prevalent that the duty of a nurse is to carry out the directions of the physician or surgeon intelligently, and that the best nurse is in general she who takes least upon herself in the way of unauthorised treatment. The author would seem to think very differently if we are to judge from the material of his book. Not only is the nurse apparently to be able to diagnose diseases but also to treat them on her own account. At least, we cannot otherwise explain the need for coloured diagrams of the various rashes which accompany the infective fevers, among which is even included so rare a condition as diphtheria of the lips, or the list of doses and actions of drugs, including a rule as to graduating the dose according to the age of the child. Indeed, in the presence of an emergency, such as heart failure, the nurse is directed to administer 1-200th grain (*sic*) of nitroglycerine hypodermically, and in asphyxia (seemingly regardless of the cause) atropine and strychnine. Some more or less complicated formulæ are also given for calculating the ingredients in artificial feeding of infants, a matter, again, which should be regulated by the physician, not by the nurse. Very vigorous treatment is occasionally recommended, as, for example, the application of "flagellation" or "spanking," to a child with bronchitis which "may be continued for several hours." We fear that some of the medical statements which the author makes to his readers are scarcely as up to date as the nurses whom he would produce. Thus, we do not think that any serious authorities will agree with him in the assertion that rheumatism is due to excess of uric acid in the system, while the statement that the night air is charged with the miasm of malaria appears to rest on an exploded theory. Indeed, the author himself admits that the bite of the mosquito is the common, but apparently not the sole, cause of infection. We have felt bound to draw attention to these features of the book, as we certainly hope that it will not be taken as a guide in these respects by any nurses in this country. Nevertheless, it has also useful features, notably the illustrations showing the nurse's part in some procedures such as intubation, tracheotomy, nasal douching, and so forth.

Grundriss und Atlas der Speziellen Chirurgie. (*Outline and Atlas of Special Surgery.*) By Professor Dr. GEORG SULTAN. Part 1. With 40 coloured plates and 218 illustrations. Munich: J. F. Lehmann. 1907. Pp. 459. Price 16 marks.—Lehmann's handbooks are very well known and we have often spoken warmly in praise of them. This new volume is a worthy follower of the others. It gives a brief sketch of the regional surgery of the head, neck, thorax, and spine; the surgery of the remainder of the body will appear in the second volume. The chief value of the works of this series lies in the illustrations, and it would be difficult to overpraise those given in this volume. The coloured illustrations are the most successful but those in black and white do not lag far behind. We commend this book to all students who read German, but even for those who are unacquainted with that language the illustrations will prove of use.

Synonymik der Dermatologie. (*A Dictionary of Synonyms of Dermatology.*) By Dr. JOHANNES FICH. Vienna and Leipsic: Alfred Hölder. 1908. Pp. 68. Price Marks 1.40. —Dr. Fich tells us that this dictionary of dermatological synonyms was started for his own use, and he has published it that it may prove useful to others. From the earliest days of dermatology it has suffered from a plethora of names and the erudition and energy of succeeding generations of dermatologists have succeeded in piling up a burdensome mass of names, which does much to deter the average student of medicine from obtaining a fair knowledge of the diseases of the skin. This dictionary should be of value in restraining the inventive ardour of the dermatologist. We suggest that at the next International Congress of Dermatologists the question of nomenclature should be considered and an attempt at uniformity might be made.

Science German Course. (University Tutorial Series.) By C. W. PAGET MOFFATT, M.A. Lond., M.B., B.C. Camb. London: W. B. Clive, University Tutorial Press, Limited. 1907. Pp. 228. Price 3*s.* 6*d.*—A fair colloquial knowledge of German is not sufficient to enable an Englishman to read scientific German, and therefore this course will be likely to prove generally useful. There are now, also, many science students who have no knowledge of German, but they have to read works in that language for the study of their branch of science; for these especially some such work as this is almost a necessity. Some very good examples of scientific German are given; they are taken from mathematics, physics, geology, chemistry, botany, and zoology, and a short vocabulary in each of these subjects is appended. We have little to criticise in the book; the only point we will mention is the sentence, "Das Gusseisen lässt sich hämmern." "Cast-iron admits of being hammered." This is certainly true in one way, but the hammering would hardly benefit the cast-iron. Probably the author intended to write "geschmiedetes Eisen," or wrought iron. The greater part of the German in the book is printed in Roman characters, for nowadays nearly all German scientific books are so printed.

JOURNALS AND MAGAZINES.

Beiträge zur Anatomie, Physiologie, Pathologie, und Therapie des Ohres, der Nase, und des Kehlkopfes. Berlin: S. Karger. Price 20 marks per annum.—This is the first number of a journal dealing with the anatomy, physiology, pathology, and treatment of the ear, the nose, and the larynx, edited by Professor A. Passow and Professor K. L Schaefer of Berlin, and it contains articles of much interest. Dr. W. Lange makes a contribution to the Pathological Anatomy of Inflammation of the Labyrinth following Middle Ear Disease. This paper will be especially welcomed by English otologists at the present time, when so much work is being done in diseases of the labyrinth, the more so as Dr. Lange gives full descriptions with the microscopical anatomy of no less than 14 cases In addition to this the article is illustrated by a most beautiful series of micro-photographs. The second article is by Professor A. Passow and deals with the closing of the bony wounds after antral operations. The next paper is by Professor Schaefer of Berlin, with tables showing the influence of various tumours on rapidity of sound travel and length of sound waves in the air, followed by one by Dr. Gutzmann on Fixation and Movement of the Larynx in Speech, Normal and Pathological. Professor A. Schultz. has a paper on the Upper Hearing Limit and its Precise Significance, while Dr. Hermann Beyer contributes a review of the Progress in the Province of the Comparative Anatomy of the Middle Ear. Few journals have started so auspiciously as this one and doubtless it will have a successful future.

THE LANCET LABORATORY.

SEPTOFORMA.

(UNION, LIMITED, 1, NORTH ST. ANDREW-STREET, EDINBURGH.)

ACCORDING to our examination septoforma is a liquid soap, containing amongst other disinfectant compounds formaldehyde. It has a distinctly alkaline reaction and a slight pungent and somewhat fishy odour. The base of the soap is, according to our analysis, potash. The preparation is agreeable to use and for the purposes of an effective antiseptic solution a dilution of 3 per cent. is sufficient. It is free from the objectionable odour of the ordinary coal tar antiseptics, while further it is a deodorant. Soap entering so largely into its composition septoforma is without corrosive or irritating action. Its practical application is reported (upon favourably.

MEMBROIDS.

EVANS, SONS, LESCHER, AND WEBB, LIMITED, 60, BARTHOLOMEW-CLOSE, LONDON, E.C.)

"Membroids" is the name given to a special administrative form of drug which secures a passage through the stomach but which is dissolved and absorbed in the intestine. In short, the drug is inclosed in a small sac made of two layers of membrane. Experiment *in vitro* readily established the resisting power of the membrane to the action of artificial gastric juice, while the contents soon escape when the membroid is placed in artificial pancreatic juice. The membrane is thus readily peptonised in the intestine but not in the stomach, and so this method is valuable when it is required to administer a drug in the intestinal tract and when that drug, as is often the case, disturbs the gastric organisation. As types of the kind of drug which it is desirable to administer by this method may be mentioned salol, aceto-salicylic acid, and various intestinal antiseptics. The idea succeeds according to clinical practice.

CUSTARD AND BLANC-MANGE POWDERS (PLASMON).

(INTERNATIONAL PLASMON, LIMITED, 66A, FARRINGDON-STREET, LONDON, E.C.)

We have before referred to the dietetic advantage gained by the addition of pure milk protein to ordinary foods. The advantage is particularly obvious in regard to those foods which contain little besides carbohydrates. The addition of plasmon or pure milk protein to these preparations is in accordance with physiological indications. The preparations are variously and pleasantly flavoured.

VARIOUS WHISKIES.

(J. AND G. STEWART, LIMITED, ANDERSON-PLACE, BONNINGTON, EDINBURGH.)

We have examined three different specimens of whisky called respectively (1) Old Highland Liqueur (Nonpareil); (2) Finest Old Vatted Scotch Whisky; and (3) Very Fine Old Vatted Scotch Whisky. Analysis readily indicated in each case that the whiskies were not entirely the product of the pot-still or of malted barley. Nevertheless, there was no indication that they contained any acrid or raw products. They are, in short, well matured and consequently smooth on the palate. The flavour was not very marked and would be described colloquially as thin. The total secondary products did not exceed in any instance 215 parts per 100,000 parts of alcohol present, though in individual examples the ethers were present in good average quantity. They represent the kind of specimens of whisky which some assert are physiologically less harmful than the full-flavoured whisky of the pot-still. The question of the suitability of a pot-still spirit for potable purposes is in our opinion almost entirely one of age. The strength of the whiskies varied from 45·41 per cent. by volume of absolute alcohol to 47·67 per cent. The extractives were in each case low.

LECITHIN (AGFA).

(CHARLES ZIMMERMANN AND CO., 9 AND 10, ST. MARY AT HILL, LONDON, E.C.)

The preparation was a viscid fluid contained in a hermetically sealed ampule. It contains a fifth of its weight of lecithin (Agfa) and four-fifths oil. It dissolved entirely in ether and on oxidation phosphate was readily obtained and recognised. We have received a copy of a paper published in the *Berliner Klinische Wochenschrift* in which the value of this preparation in nervous disorders, tabes, paralysis, and so forth, is referred to.

ATOXYL.

(R. W. GREEFF AND CO., 20, EASTCHEAP, LONDON, E.C.)

Atoxyl represents the most recent form of administering arsenic in organic combination. Its value in trypanosomiasis is well known, but its administration is being extended to other cases of disease in which arsenic has been administered with favourable results. Atoxyl is chemically meta-arsenic anilide and according to the formula $C_6H_5NHAsO_2$ contains 37·67 per cent. of arsenic. We had no difficulty in converting the arsenic into an inorganic form by oxidation and then recognising it by the ordinary tests. Amongst the specimens received were Blaud's atoxyl capsules (each containing three-quarters of a grain atoxyl), atoxyl tablets, and atoxyl sterilised solution for subcutaneous injections. The last was contained in ampules hermetically sealed.

ROYAL FACHINGEN MINERAL WATER.

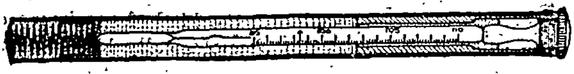
(AGENTS, 6, GREAT ST. HELENS, LONDON, E.C.)

This water, drawn from the springs at Fachingen in the province of Hessen-Nassau, Germany, is peculiarly soft and agreeable to the palate and effervesces slightly with carbonic acid gas. It is distinctly alkaline in reaction and contains in fact the carbonates of the alkaline metals, sodium, magnesium, calcium, and lithium. According to our analysis the total amount of saline constituents per litre was 2·424 grammes. Of this 2·26 consisted of the alkaline carbonates and the rest was chiefly common salt. There were present also traces of bromides and sulphates. The water belongs to that group of mineral waters a course of which is of value in those diseases which are characterised by catarrh of the mucous membrane. Fachingen water has a reputation also in the treatment of chronic catarrh of the bladder and urinary passages.

New Inventions.

AN ANTISEPTIC THERMOMETER CASE.

I SUGGESTED recently to Mr. R. Forge the need of an effective antiseptic thermometer case, and acting on our instructions Messrs. Arnold and Sons have made such a case, its object being to keep the clinical thermometer completely immersed in a dilute antiseptic, when not in use, in the pocket. The case consists of five parts: (1) an outer case, (2) a screw cap, (3) an inner case, and (4) a valve which is supported by (5) a nickel-plated brass spring. It will thus be seen from the illustration that (1) the thermometer while in the case is completely immersed in fluid, and (2) on removing the cap the thermometer rises automatically from the case, the spring-controlled valve closing beneath it, so that none of the fluid can escape. An arrangement is to be fitted into the case by means of which the thermometer will be wiped automatically comparatively dry as it rises up on removing the cap. Two further advantages are attained: (1) the parts of the case can be separately sterilised; and (2) the thermometer, being spring-supported, is less liable to be broken if the case is dropped.



This illustration represents half of the actual size. The case is therefore no larger than a fountain pen, which it can be decorated to resemble. It is made of ivory-grained xylonite, and being white and slightly translucent its working can be seen against the light. Messrs. Arnold and Sons have carried out our ideas in a most careful and satisfactory manner.

S. SMULIAN, M.R.C.S., L.R.C.P. Lond.

Dalston, N.E.

BRITISH MEDICAL BENEVOLENT FUND.

AT the June meeting of the committee 16 applications for help were considered and grants amounting to £170 were made to 15 of the applicants. Appended is an abstract of the cases relieved.

M.D. Lond., aged 66 years. No means, and has been incapacitated for the last few months by paralysis. Two children, aged seven and two years. Voted £18.

Widow, aged 38 years, of L.R.C.P., L.R.C.S. Irel. Quite unprovided for at husband's sudden death two years ago, and now acts as working housekeeper without a salary on a small farm in Ireland. Three children, aged 12 to four years, the two elder being supported and educated by relatives and the younger by the applicant. Voted £10.

M.R.C.S., L.R,C.P., aged 73 years. For several years past has been in bad health and recently had to undergo a serious operation. Now endeavours to support himself and wife by acting as locum tenent. Living in one room, for which three months' rent is owing. No children. Voted £18.

Daughter, aged 59 years, of late M.R.C.S. Receives a Government pension of a few shillings a week and a small yearly grant from a charitable fund. Health very delicate and no relatives who can help. Relieved 11 times, £65. Voted £5.

Widow, aged 45 years, of L.R.C.P., L.R.C.S. Edin. Quite unprovided *for at husband's death* a few years ago. Keeps a small school, but the fees are only a few shillings weekly. Has to provide a home for three out of six children, who contribute as much as their salaries allow. Relieved five times, £60. Voted £10.

Widow, aged 61 years, of L.R.C.P., L.R.C.S. Edin. No income. Used to support herself by taking boarders, but is now dependent on a daughter earning her own living and obliged to be away from home. Relieved once, £12. Voted £12.

Daughter, aged 48 years, of late M.R.C.S., L.S.A. No income. Subject to frequent epileptic seizures which quite prevent any successful attempt to earn a living. Relieved five times, £60. Voted £12.

Widow, aged 60 years, of M.D. St. And. No income. Endeavours to support herself by letting lodgings. Children only able to give very slight help. Relieved four times, £48. Voted £12.

Widow, aged 70 years, of L.F.P.S. Glasg. After husband's death used to support herself by taking resident patients, but is now unable to do this and is dependent on a small weekly allowance made by a son who is a clerk. Relieved once, £12. Voted £5.

Orphan, aged seven years, of late L.R.C.P., L.R.C.S. Edin. At father's death three years ago was taken to the workhouse but was removed by an uncle with whom she now lives but whose earnings are less than 30s. a week. Relieved once, £9. Voted £9, payable to the uncle.

Daughter, aged 62 years, of late L.S.A. Has supported herself for many years as a governess but is now dependent on a small annuity given by a society. Relieved 10 times, £92. Voted £12.

Widow, aged 43 years, of M.R.C.S., L.R.C.P. Income £25 a year. Attempted to support herself by taking boarders but was unsuccessful and now asks for a contribution towards the expenses of returning with her two children to the West Indies, where she has relatives who can help. Relieved once, £5. Voted £5 towards passage money if the relatives will find the balance.

Daughter, aged 62 years, of late M.R.C.S., L.S.A. Mentally deficient and dependent on relatives who can ill afford to help. Relieved twice, £24. Voted £12.

Widow, aged 59 years, of L.F.P.S. Glasg. No income. Endeavours to support herself by selling sweets on commission for a wholesale firm, but owing to ill-health of only daughter, a governess, is in arrears with the rent of her room. Relieved once, £18. Voted £18.

Widow, aged 57 years, of L.R.C.P., L.R.C.S. Nearly blind. No children. No income. Relieved 14 times, £125. Voted £12.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

THE annual election of members of Council was held on July 2nd at the College in Lincoln's Inn-fields. There were four vacancies and the following Fellows were candidates: Mr. A. Pearce Gould and Mr. W. Harrison Cripps, who applied for re-election, and Mr. George Eastes, Mr. Bilton Pollard, Mr. W. F. Haslam, Mr. C. B. Lockwood, Mr. W. Arbuthnot Lane, and Mr. J. Lynn Thomas, in order of seniority. The voting began at three o'clock and the poll was open for two hours, but only 13 Fellows voted in person. 843 votes were received by post and of these one was invalid and two were too late. The counting of the votes took over one and a half hours and the following was the result:—

	Votes.	Plumpers.
Mr. A. PEARCE GOULD	484	8
Mr. W. ARBUTHNOT LANE ...	406	72
Mr. W. F. HASLAM	331	22
Mr. C. B. LOCKWOOD	331	17
Mr. G. EASTES	320	15
Mr. W. HARRISON CRIPPS	279	3
Mr. BILTON POLLARD	243	11
Mr. J. LYNN THOMAS	219	12

The PRESIDENT declared Mr. Pearce Gould to be re-elected and Mr. Arbuthnot Lane, Mr. Haslam, and Mr. Lockwood to be elected members of the Council of the College.

Mr. H. J. Price and Mr. T. Crisp English acted as scrutineers.

THE MEDICO-LEGAL SOCIETY.—The second annual dinner of this society will be held at the Holborn Restaurant, London, on July 22nd, at 7.30 P.M. The President, Mr. Justice Walton, will be in the chair, and it is expected that several distinguished guests will be present. Tickets (half-a-guinea each) for members and their friends may be obtained from the honorary secretaries, Dr. S. B. Atkinson, 10, Adelphi-terrace, W.C., and Mr. D. Cotes-Preedy, 2, Elm-court, Temple, E.C.

THE LANCET.

LONDON: SATURDAY, JULY 11, 1908.

Preservatives in Meat Foods.

THE report recently issued by the Medical Department of the Local Government Board on preservatives in meat foods packed in cans or glass seems to us to demand a fresh consideration of the whole question of food preservation by chemical means. The temptation to use preservatives must be very strong when, as this report states, they are found to be present in meat foods which are submitted to a process of sterilisation. The obvious suggestion is that the preservatives are used for an undesirable purpose. Apart from the questions as to whether certain preservatives are or are not harmless, their presence in the circumstances just stated probably signifies that the meat required some kind of treatment in order to correct an unwholesome condition in regard to it or to negative perhaps an undesirable change which may threaten to take place during the process of manufacture. It is quite clear at any rate that sterilisation must be the last operation concerned, because that can only be done when the foods are hermetically sealed in the tins. Preservatives are therefore used probably as a preliminary precaution to keep the meat in a condition which, at any rate, makes it appear to be wholesome. Various circumstances which we are told come to light from time to time as the result of action by local authorities suggest that a lucrative trade is sometimes done in meat which has been purchased at a time when fresh meats have reached the limit of their keeping powers. This fact opens up a promising field for the manufacturer of preservatives who loses little opportunity in pressing the claims of his goods upon those engaged in the various branches of the trade in meat-food products. As Dr. A. W. J. MACFADDEN points out in his report, these antiseptic materials are often sold under fancy names, with nothing to guide the purchaser as to their composition, and are often accompanied by a sort of guarantee to the effect that their use in accordance with directions given will not entail liability to prosecution. There can be little doubt that the great saving in trouble and material which is held out as an inducement to users of these substances and the harmless, not to say beneficial, effects which they are stated to have on those who consume them in food have had weight with a certain class of manufacturers of preserved meat.

Another interesting and important point alluded to in the report is the penetrative power of preservatives when used as a packing material. It appears from a number of experiments made by Mr. P. A. ELLIS RICHARDS, F.I.C., that boric acid, for example, which has bee[illegible] with hams for a period of three or four we[illegible] more does actually penetrate their substance to a very considerable degree. Such a definite result disposes entirely of the contention that penetration beyond the surface, except to the smallest extent, does not take place. Moreover, the samples of hams dealt with were washed and brushed before the chemical examination was started, and notwithstanding this treatment there were found in the skin covering the fat as much as from 13 to 24 grains of boric acid per pound, and in the outer half-inch of the lean side of the hams amounts varying from 19 to 45 grains per pound. Even after boiling in the way ordinarily employed large amounts of boric acid were still observed to be present in the outer layers of the lean portions of two hams. Throughout the entire mass of the meat the preservative was demonstrated and even in the most remote parts of the muscular substance quantities varying from two to 15 grains per pound were noted. While, however, muscular tissue appears to be liable to extensive penetration the amount absorbed by the large mass of fat forming the upper portion of the ham is small.

The lessons of this report are striking enough and the opinion which we have often expressed in these columns that the protection afforded to the British public against preservatives in foods is far from being adequate again receives endorsement. This country has not even settled for itself official standards in regard to this matter and at the present time only the recommendations of a departmental committee which reported eight years ago can be referred to as being to some extent authoritative. These recommendations need to become statutory, and British requirements should be specified in such a way that foreign and colonial manufacturers and officials can have no difficulty in understanding as to what the public health authorities in this country expect them to avoid or to do in regard to the use of preservatives.

◆

The Recent Low Urban Death-rate.

JUDGED by the low mean rate of mortality during April, May, and June, in the 76 large English towns for which the Registrar-General publishes weekly returns, the health condition of their aggregate population, now exceeding 16,000,000, was exceptionally favourable during the past spring quarter. The mean annual death-rate in these towns during the 13 weeks ending on June 27th did not exceed 13·8 per 1000, against an average rate of 15·0 in the five preceding corresponding periods of 1903–07, the lowest rate in these five spring quarters being 14·7 per 1000 in 1905. The mean temperature of the air at the Royal Observatory, Greenwich, during the 13 weeks was 52·4° and 0·3° below the average temperature of the same period in 65 years. The mean temperature was considerably below the average in April, and was slightly below the average during the last three weeks of June; whereas a considerable excess of temperature prevailed during May and the first week of June. The measured rainfall at Greenwich was 6·06 inches, exceeding the average in

an half an inch. The
ne during the 13 weeks
rded amount in the same
urs, and the average amount
of recent years by 87½ hours.
unfavourable effect on the public
nably cold and trying weather in
ssive mortality from diseases of the
s and increased fatality of measles
cough, was fully counterbalanced by the
effe exceptionally fine weather and bright sunshine
during ay and the greater part of June. It does not, however, appear that any considerable proportion of the marked reduction in the rate of urban mortality during last quarter can reasonably be attributed to unusually favourable meteorological conditions. The mean annual death-rate from the principal epidemic diseases in the 76 towns during the quarter did not exceed 1·12 per 1000, against 1·45 and 1·58 in the corresponding periods of 1906 and 1907. The recorded deaths in these towns from measles, scarlet fever, diphtheria, whooping-cough, "fever," and diarrhœa during last quarter were from each disease considerably below the mean number in recent corresponding periods. Infant mortality in these towns, which had been equal to 108 and 110 per 1000 births registered in the spring quarters of 1906 and 1907, declined to 100 per 1000 in the quarter just ended. These facts seem to point conclusively to continued improvement in the sanitary condition of our large urban population. It is not without interest to note that while the death-rate during last quarter did not exceed 13·8 per 1000 in the 76 English towns, it was equal to 16·4 in the eight principal Scotch towns, and to no less than 20·1 in the 22 Irish towns respecting which the Registrar-General for Ireland reports weekly; thus, compared with the mean rate in the English towns the urban death-rate showed last quarter an excess of 18·8 per cent. in the Scotch towns and of 45·7 per cent. in the Irish towns. Having regard to the fact that the mean population of both the Scotch and the Irish towns is considerably smaller than that of the English towns, the marked excess of urban mortality in Scotland and Ireland forcibly suggests the conclusion that improved sanitation has not made the same progress in those parts of the United Kingdom as in England and Wales. A comparison of the mortality statistics of London, Edinburgh, and Dublin points to the same conclusion. The death-rate among the nearly 5,000,000 of persons residing within the County of London during the 13 weeks ending on June 27th last did not exceed 13·3 per 1000; whereas in Edinburgh, with an estimated population of 350,524, the death-rate was equal to 15·5, and in Dublin, with an estimated population of 394,525, it was equal to 20·1 per 1000. Thus in equal numbers living, for each 100 deaths registered last quarter in London 117 deaths occurred in Edinburgh and 153 in Dublin. This startling excess of recent urban mortality in Ireland, which cannot unfortunately be regarded as exceptional in view of the light thrown upon defective sanitary organisation by the recent Belfast report, urgently calls for exhaustive public inquiry.

The Treatment of Shock.

THERE are many problems in surgery in the solution of which physiological experiment can be of the greatest service. Empirically there has grown up a mass of therapeutic measures designed to deal with complications that may occur, and in regard to most of these it is difficult indeed to say which are really of value. There is probably no more common cause of death after operation nowadays than shock. Thanks to modern surgical methods sepsis has lost its former pre-eminence as a cause of death in cases where an operation has been performed, but in the prevention and treatment of shock little progress has been made until recently. Every surgeon and every anæsthetist has certain methods of treatment of shock, but many of them fail utterly when put to the test. The vital importance of the matter must be acknowledged by all, for it may be that the very methods which we employ are increasing in place of retarding the shock which we try to treat. Here is the office of applied physiology; by judicious experiment we can investigate the true value of our methods of treatment and then our therapeusis will rest on a firm basis. In a paper recently read before the London Hospital Medical Society and published in our columns (see p. 85) Mr. A. J. WALTON showed conclusively the immense value of the aid that physiological experiment can give to surgery in the solution of these difficult problems.

All pathologists are now agreed that in shock there is a marked fall of blood pressure and that this fall is brought about partly by the weakening of the heart but chiefly by a great dilatation of the vessels of the splanchnic area. Some use the term collapse as synonymous with shock, but more generally it is applied to the condition when the shock has had added to it a marked loss of blood or a loss of fluid from the vessels by transudation. The fall of blood pressure is due to the trauma which acts by impulses conveyed by the afferent nerves to the vaso-motor centres, and this is shown by various facts. The amount of shock is directly proportional to the amount of injury to the nerves of a region, and, further, the more specialised and the more abundant the nerve-supply of a part the more readily is shock produced when that part is subjected to injury. Cutting a limb produces much less shock than crushing a limb. When previously to the injury the main afferent paths are cocainised the resulting fall of blood pressure and shock are of little importance, even when severe injury is employed. The most significant fact is that the amount of shock depends on the part injured. In some parts, as the skin of the limbs, the first effect of an incision is to cause a rise of blood pressure, but as the injury increases in severity the rise is replaced by a fall. When the abdomen is opened the mere incision of the tissues of the abdominal wall and the exposure of the contents of the abdomen are sufficient to produce a marked fall in the peripheral blood pressure with symptoms of shock; this fall can be at once checked by the application of warm saline solution to the peritoneal cavity. Experiments show that this fall of blood pressure resulting from injury is due to paralysis of the vaso-constrictor centre. We have, therefore, been enabled to obtain a very exact notion of the essential nature of shock: it is a decrease in blood pressure, which is caused by dilatation of the splanchnic area, resulting from multiple afferent impulses; these afferent impulses may cause a temporary action of the vaso-constrictor centre, but the centre is soon paralysed and the peripheral vessels dilate. A further complication may be present—a decrease in the total amount of the fluid constituents of the blood, and this materially increases the difficulties of the circulation. These experimental results have been obtained from animals, but all observations show that the conditions are the same in man. In an excision of the breast with much traction on the brachial plexus the blood pressure has been observed to fall from 135 to 60 millimetres of mercury. The chief factors which determine the amount of shock are of importance. As the length of the operation increases, the fall of blood pressure increases also; and it is clear that, so far as is consistent with efficiency, the operation should be as brief as possible, especially in the old, in the ill-fed, and in the debilitated. The organ involved is of the greatest moment in determining the amount of shock, and when the abdomen or brain is involved the fall of blood pressure is very great. Anæsthetics have much influence and their action is two-fold. Inasmuch as they produce unconsciousness, they block the afferent impulses and thus have a very definite effect in diminishing shock. It must not, however, be forgotten that an anæsthetic may in itself have a toxic action on the vaso-constrictor centres. With ether there is no fall but a steady rise of blood pressure throughout the whole course of the operation, and this is not due to any stimulant action of the drug. If any fall occurs it is due to the operation itself. On the other hand, the administration of chloroform is accompanied by a steady fall of blood pressure from the very beginning of the operation to the end. This fact is of very great importance. Spinal anæsthesia has been shown not to cause *per se* the slightest fall in blood pressure, and even in old and exhausted patients operations may be performed under spinal anæsthesia with remarkably little shock.

All this is the theory of shock in operations; how can we apply it in practice? We must start from the preparation of the patient for operation. Drastic purgation must not be employed, for it has a very definite effect in lowering blood pressure, and prolonged fasting previously to an operation is equally or even more harmful. Whenever possible ether should be preferred to chloroform, or if ether be contra-indicated spinal anæsthesia should, from the point of view of prevention of shock, be employed when possible. CRILE devised a "pneumatic suit" in which the patient is enveloped and pressure is maintained on the surface; this certainly tends to diminish shock but we are not aware that it has been much employed. Cocaine has been injected into the main nerve trunks previously to large amputations, and the fall of blood pressure has been greatly reduced; the method seems to be worthy of a trial in suitable cases. The maintenance of the bodily heat is also of importance, though it has not been shown that loss of temperature is a definite causative factor. All these methods of treatment are preventive; but what can be done when shock has already appeared? If there is one remedy which is trusted more than
shock it is strychnine, yet all s
it seems to fail in all the cases in
In health strychnine will raise
stimulating the vasomotor centre, but in
tration of this drug will only serve to ex
rapidly the damaged centre, so that if shoc
strychnine is not only useless but positively d
Other stimulants are equally valueless, and with ether and brandy the fall of blood pressure is even more marked, for these drugs cause a dilatation of the peripheral vessels. Cardiac stimulants will affect only one factor concerned in the maintenance of blood pressure, and increased action of the heart cannot compensate for any marked relaxation of the peripheral resistance. Suprarenal extract has a very evident effect in contracting the peripheral capillaries and so raising the blood pressure, but its effect is transient; and Mr. WALTON is of opinion that the best method of administering it is by continuous rectal injection in saline solution, one drachm of solution of suprarenal extract to a pint of the saline solution—that is to say, 1 in 160,000; the temperature of the liquid should be between 108° and 112° F. and it should be allowed to flow in at the rate of one pint an hour. Ergot, too, is valuable and its effects last longer. The injection of saline solution into the veins or subcutaneous tissue is of very definite value but it can easily be overdone, and Mr. WALTON considers that the maximum amount that may be given intravenously is three pints and by continuous rectal injection not more than from five to eight pints. Raising the foot of the bed 18 inches or two feet tilts the blood from the splanchnic area towards the brain but it would hardly be suitable in a case of localised septic peritonitis. The main doctrine of the paper may be summarised by saying that stimulants of all kinds, but especially strychnine and brandy, must be avoided both before and during an operation; they can have no effect in diminishing shock and they may easily increase it. These facts should be laid to heart by surgeons and anæsthetists, for they rest on a very sure basis of fact. Almost equally important was the second part of the paper in which the author dealt with the rare condition which has been called "peritonism," where all the signs of intestinal obstruction are present but no mechanical obstruction exists. The occurrence of such a condition has been denied but cases of it undoubtedly do occur and they are caused by a paralysis of the bowel. We have not space to follow Mr. WALTON through his discussion of the etiology and treatment of this serious condition but we may draw attention to his recommendation of eserine salicylate which acts directly on the intestinal muscular tissue and not on the exhausted intestinal nerve plexus; it has proved of value in several cases; a dose of one-hundredth of a grain appears to be suitable and six doses may be given. It is curious that in health eserine has hardly any effect on the intestine but it is probable that it can only act when the local centres are paralysed. Mr. WALTON'S paper should be read by all who have to deal with shock; it can hardly fail to prove useful in the treatment of this most serious condition.

Annotations.

"Ne quid nimis."

THE TOXICITY OF TOBACCO SMOKE.

SOME years ago we pointed out in these columns that tobacco smoke contained quite a large proportion of the poisonous gas carbon monoxide. If a mere mouthful of tobacco smoke be blown upon a dilute solution of blood a pink colouration at once appears which is characteristic of the compound formed when carbon monoxide unites with hæmoglobin and spoils its healthy function. Subsequently it has been shown that the proportion of carbon monoxide in tobacco smoke is considerable, and it is a question whether nicotine can be held to be responsible at all for the symptoms summed up in the words "tobacco-smoke poisoning." At all events, it is well known that though nicotine exists in tobacco yet a very small proportion of it appears in the tobacco smoke. Undoubtedly there are poisonous oils present, chief of which is pyridin. Pyridin apart, however, it is certain that one of the abundant products of combustion (or rather of incomplete combustion which the production of smoke implies) is the poisonous gas carbon monoxide. It has been calculated in practical experiments that one ounce of tobacco when smoked in the form of cigarettes gives as much as from one pint to four pints of carbon monoxide gas, while the same amount of tobacco smoked in a pipe gives from two and a quarter to five pints of the gas. So far it would appear that the pipe ought to be more pernicious than the cigarette if it were not for the fact that it is practically only with the cigarette that inhalation of the smoke is indulged in. The symptoms of carbon monoxide poisoning resemble in a noteworthy manner the symptoms of tobacco-smoke poisoning. The excessive smoker often develops, for example, a tendency to dizziness and shortness of breath on exertion; there are evidences also of heart disturbance, and he is troubled often enough with palpitation, or, at least, a consciousness of the heart's beating, and the senses, power of judgment and of movement are frequently impaired. In some respects the symptoms of carbon monoxide poisoning resemble those produced by an immoderate or chronic indulgence in alcohol. There can be little doubt, therefore, that the association of smoke and drink is a poisonous one, both conspiring to bring about similar toxic effects. When we consider the quite large amount of carbon monoxide present in tobacco smoke, and compare with this fact that as little as 0·17 per cent. of the gas in the air is fatal to animals, though usually 0·4 per cent. is required, and that anything above 0·15 per cent. is regarded as distinctly dangerous, it is obviously within the bounds of probability that tobacco smoke can be very harmful on account merely of this gaseous constituent. If that is so, what a serious complexion does the habit of inhaling tobacco smoke assume, in which procedure the smoke and the carbon monoxide contained in it are introduced directly into the circulatory system. These facts call forth also an interesting reflection on the headache and drowsy and stupid feelings of the person who has been shut up in a "smoker" on the railway train or in the badly-ventilated atmosphere of the smoking-concert room.

SOME AMERICAN PROPRIETARY REMEDIES.

AT the recent annual meeting of the American Medical Association at Chicago an interesting exhibit was given by the Bureau of Chemistry, Washington. It consisted of samples of packages of a number of medicinal preparations which have been examined by the chemists in the bureau, with brief analytical notes. Of the so-called "prescription proprietaries" Kargon Compound and Marmola were shown; of these the former was found to contain fluid extract of buchu, potassium acetate, methyl salicylate, and sugar, while the latter consisted of thyroid glands, powdered senna, extract of poke root, extract of bladder wrack, citric acid, and sugar. A dentition syrup for babies sold under the name Espey's Syrup was found to contain cocaine; the printed label bore a statement to the effect that half a grain of cocaine muriate was present. A preparation known as Make-man Tablets, which is extensively pushed in the United States, gave evidence of the presence of iron, arsenic, valerianic acid, and hops. A French remedy, Mixture Anti-diabetique (Martin) appeared to consist of apricot kernel oil, and an "anti-gonococcide," known as Serum Bautier, was found to be not a serum at all but a solution of magnesium iodo-phenol sulphonate. Goat Lymph Tablets were found to contain strychnine phosphate, zinc sulphide, extract of muira puama, avenin, and cannabin. Another preparation, styled East Indian Consumption Cure, which claimed to contain cannabis indica as the chief constituent, actually consisted of cinchona bark, opium, ipecacuanha, and Rochelle salts. Liquids labelled Blue and Red Electricity, made in Italy, apparently contained nothing more than ordinary tap-water. Many preparations were shown about which extravagant claims have been made by the proprietors. Of these, Asandrin appears to be a perfumed solution of quinine sulphate with precipitated sulphur; Compound Quinoleum, a mixture of the tinctures of capsicum, cantharides, and cinchona with resorcin; Egg-O-Tone consists largely of Epsom salts and borax with a little sulphate of quinine; Toris Root Compound is a mixture of sodium salicylate, potassium nitrate, and sugar; and Cotandin Compound consists principally of cascara sagrada, hydrochloric acid, and water.

CONVERSAZIONE AT THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ON July 2nd a conversazione was held at the Royal College of Physicians of London, Pall Mall East, when the President, Sir Richard Douglas Powell; the Censors, Dr. D. Ferrier, Dr. J. Mitchell Bruce, Sir T. Clifford Allbutt, and Dr. J. F. Goodhart; the Treasurer, Sir Dyce Duckworth; the Registrar, Dr. Edward Liveing; the Librarian, Dr. J. F. Payne; and a number of Fellows, including Dr. F. W. Pavy, Sir Lauder Brunton, Sir James Reid, and Sir Felix Semon, were present to entertain a number of guests. Among those accepting invitations were the Archdeacon of London, the Vice-Chancellor and the Dean of the Faculty of Medicine of the University of London, the Vicar of St. Martin's-in-the-Fields, the President and Vice-Presidents of the Royal College of Surgeons of England, the President of the Medical Society, the President of the Royal Society of Medicine, the Treasurers of the Hon. Societies of the Middle Temple and of Lincoln's Inn, Professor Sir E. Ray Lankester, the President of the British Medical Association, the Director of the Lister Institute, Surgeon-General A. M. Branfoot, Mr. A. Denman, and a large number of Licentiates. Invitations were sent to all Licentiates of the College who obtained their diplomas prior to the year 1893. During the evening the band of the Royal Artillery played a well-chosen programme of music, while the collection of pictures in the College, itself a noteworthy one, was reinforced by works of art lent for exhibition by Sir Charles Holroyd, Sir John Scott, Mr. Alfred Parsons, Messrs. Dunthorne, Messrs. Colnaghi, and various Fellows of the College, Sir Thomas Barlow, Dr. Norman Moore, Dr. T. Buzzard, Dr. Ferrier, Dr. Seymour Taylor, Sir

William Allchin, and Dr. Payne, among others. The art collection was arranged by Dr. F. G. D. Drewitt, several of whose delightful water-colours were on exhibition, other artistic Fellows whose work was displayed being Dr. Buzzard and Dr. W. R. Dakin.

THE DANGERS OF MERCURIAL INJECTIONS.

Fatal results from injections of mercury in ordinary doses have now been frequently recorded. In France they have often been reported from injections of "grey oil," a preparation of metallic mercury much used in that country. At a meeting of the Société Médicale des Hôpitaux of Paris on March 27th Professor Gaucher reported the following case and *à propos* of it described a form of stomatitis which he regards as peculiar to injections of grey oil and not produced by other preparations of mercury. Gangrene of the mucous membrane of the gums occurs and extends more or less to the mucous membrane of the pharynx, and extending also in depth produces gangrene of the cellular tissue of the neck and necrosis of the lower jaw. Professor Gaucher has found that this variety of stomatitis is unilateral and occurs much more frequently on the right side. It is very fatal and appears to be a variety of the grave mercurial stomatitis of the fifteenth century. A man, aged 45 years, went to hospital on March 22nd, 1907, with all the symptoms of tabes. He had contracted syphilis 20 years previously. Injections were given daily of 0·02 centigramme of benzoate of mercury. In August he ceased to attend, but he returned on Jan. 23rd, 1908, with severe mercurial stomatitis. He could open his mouth with difficulty; the tongue was swollen and the mucous membrane of the mouth was turgid, ulcerated, and covered with saliva which flowed away continually. He had been treated for two months in another hospital and had been given nine injections of grey oil. After the seventh the gums became painful and the pain increased after the eighth. Nevertheless the ninth injection was given. The injections were properly administered and there was no albuminuria. The tabetic symptoms were scarcely affected. Frequent lavage of the mouth with oxygenated water, painting the ulcers with tincture of iodine, and iodo-tannic syrup internally were prescribed. The stomatitis improved a little, but suddenly, on Feb. 11th, it assumed its former severity. A gramme of iodide of potassium was prescribed daily. On the following day, when the inflammation was reduced a little, a greyish gangrenous ulcer could be seen on the mucous membrane of the right cheek, which extended on one side to the gum and border of the tongue and on the other to the palate. In the position of the molar teeth, which were absent, was a greyish sequestrum of the inferior maxilla. In the right submaxillary region was a hard swelling which extended on the external surface of the jaw. The urine contained a trace of albumin and a very small quantity of mercury. The presence of the latter more than a month after the cessation of the injections showed that there was still a source of intoxication. In the right buttock a nodule was found which evidently contained a supply of mercury. On the 27th this was removed and the submaxillary swelling was incised, which caused the escape of sero-sanguineous fluid from the œdematous tissues. The incision was sutured and drained. Slow improvement followed. On March 25th and 26th two large sequestra were removed with forceps. Professor Gaucher pointed out the special danger of injections of grey oil as compared with injections of more soluble preparations. The mercury might accumulate and then suddenly undergo absorption with disastrous results. Thus in a case recorded by M. Lefulle 21 injections were given almost weekly during a period of four months. Only after an interval of 20 days did the last injection provoke fatal stomatitis. In a recent case reported by Professor Gaucher to the Société de Dermatologie 15 injections were given without interruption; then symptoms similar to those of the case related above occurred and terminated fatally. The *forme spéciale de stomatite mercurielle* produced by injections of grey oil has, according to Professor Gaucher, the following characteristics. It begins like an ordinary generalised stomatitis. Then the severity of the symptoms diminishes and the stomatitis becomes localised and necrosis occurs at a point in the maxilla over which the soft parts ulcerate and slough. The bone and the tissues covering it swell and a submaxillary induration is formed. If improvement does not occur the gangrene extends towards the pharynx and trachea, œdema of the glottis results, and tracheotomy becomes necessary. Death from general infection, broncho-pneumonia, or hæmorrhage from ulceration of vessels follows. Treatment consists, in addition to the ordinary measures for stomatitis, in excision of any nodules due to the injections which can be felt or are revealed by radiography, and in incision and drainage of the submaxillary swelling to permit the escape of serum and to prevent œdema of the glottis. But more important is prevention—the disuse of injections of insoluble preparations of mercury.

AN IRISHMAN ON LUCK.

Dr. Maurice Hime is well known to our readers as the head-master of Londonderry School, who for many years has laboured with his pen to improve the moral and physical conditions of his fellows. He has forwarded to us two of his latest publications; the larger of these is an essay upon Luck[1] which he defines at the outset as "an unforeseen occurrence that brings one some advantage, in the happening of which one has had, consciously to oneself, no hand, act, or part," with the reservation that there really is no such thing as "luck" which is nothing but a convenient expression to cloak our ignorance of the How and Why of various occurrences which change the current of our lives. Dr. Hime's thesis is that there is no "luck" in the social and material advantages to which a man may be born, but that to nearly every man, in his life-time and in his degree, real luck holds out a hand, and he who has the sense and energy to grasp it is the so-called lucky man. He quotes a chapter of instances, some truly remarkable, within his own recollection in each of which a stroke of luck has befallen a man and has proved the starting point of a successful career, but he insists that these successes were far more the result of readiness to seize an opportunity than of the occurrence of the opportunity itself. He draws his illustrations from many ranks in life, and he carries his conviction that success attends merit rather than luck so far as to defend the expert golfer who holes out his ball with his tee shot against the accusation of owing his achievement to a mere piece of good fortune. We are inclined to think the author shows a little of the optimism of his race in his estimate of the rewards of simple merit and hard work, especially when he comes to consider the chances of distinction open to an ambitious youngster of low degree. Even in these days of university extensions there must be many a Jude eating out his heart in bitter obscurity, whilst in more favoured classes the quality of pushfulness, though hardly a cardinal virtue, must surely be held accountable for a considerable measure of success in life, and, indeed, to hold the secret of much apparent luck. Surely, too, ill-gotten gains have not always brought their possessors to grief, though they may certainly not have brought such happiness as was worth their acquisition. But Dr. Hime's book is an admirable sermon, and it enforces the oft-forgotten lesson that when "there is nae luck aboot the hoose" it is chiefly the householder who is to blame. Dr. Hime, doffing the philosopher's robe for the councillor's gown, seeks to hammer this important truth into his fellow-townsmen's heads by a little pamphlet cast in catechism form concerning the health and the water-supply of Derry. He considers that ill-luck of the gravest will befall that city if it remains apathetic to the repeated advice of sanitary experts on the need for reforming its water-supply, which has been shown to be quite inadequate in both quantity and quality, and for which an alternative scheme has been proposed. He condemns unreservedly the hygienic sins which are daily committed in the sewage disposal of Londonderry and draws the conclusion that its present death-rate of 17 per 1000 could be reduced appreciably if the civic fathers could be persuaded to pay some heed to the frequent warnings of its medical officer of health. We should like to see a few more laymen with such an intelligent grip of the subject as Councillor Hime possesses, stating the case for communal hygiene with the force of this catechism. A sentence from the answer to its question: "How can we make Derry as perfect a city in regard to health as it is possible to make it?" might be written up with advantage in every council chamber in the kingdom. It runs: "Let us practice economies, by all means, in every direction, consistently with dignity and decency. But whatever economy we practise let it not be at the expense of the health and strength—yea, the very lives of our fellow-citizens." In the safeguarding of men's lives from the assaults of polluted air and foul water luck can play no part, liberal foresight and constant watchfulness can alone avail to meet them.

[1] Luck: An Essay on Its Unimportance as an Auxiliary to Success in Life. By Maurice C. Hime, M.A., LL.D. Dublin: Hodges, Figgis, and Co. London: Simpkin, Marshall and Co. Pp. 105. Price 1s.

UNRECOGNISED FRACTURES OF THE HIP.

IN the *Journal of the American Medical Association* of May 16th Dr. A. Soiland has called attention to the fact that fractures of the hip are more common than is supposed and not infrequently are diagnosed as sprains or bruises. The mistake is due to the facts that the cause of the injury is slight, such as a fall from stumbling over an obstacle, that the fragments are often impacted, and that there is such a small amount of shortening that it is undetected. The use of the x rays shows the true nature of such cases. Within the past two months Dr. Soiland has seen three cases in which the mistake was made. The patients limped into his room with only the assistance of a cane. One sought electric treatment for pains about the joint and the others came for a diagnosis by means of the x rays. In one case the patient was a man, aged 40 years, in good health. He was wrestling with a friend and they both fell to the ground. The friend got up unhurt but the patient rose with difficulty, felt weak, and had acute pain in the hip on which he had fallen. Supported by his friend he walked a short distance to a physician's house. As there appeared to be no reason to suspect fracture he was hurriedly examined. A liniment and a few days rest in bed were prescribed. After a week he returned to work, with the hip somewhat swollen and painful. He was able to get about fairly well with a cane. However, after six weeks of more or less suffering he went to Dr. Soiland for electric treatment. A radiogram showed impacted fracture of the neck of the left femur. There was nearly an inch of shortening and the patient still complained of pain from using the leg much. The soft parts about the joint were enlarged and bony union was firm. In the second case a woman, aged 48 years, fell out of bed on the thigh and hip. Though the fall was so insignificant the pain was so great that she went to bed and called in a physician who diagnosed injury of the ligaments of the hip. Hot applications were advised for a few days, after which she was told to get up and to exercise the leg. This caused severe pain and the patient complained that the leg would not bear her weight. As improvement was slow several other physicians were called in who all confirmed the first diagnosis. Meanwhile the hip remained painful and became more swollen and unable to support the body. Electricity was applied and exercise carried out every day but the hip got worse and the general health failed. Change of air was then advised. A skiagram showed an impacted fracture of the neck of the femur. In the third case a man in stepping out of a motor-car fell and injured his hip. A practitioner examined him under anæsthesia and found the femur dislocated, the head lying on the anterior lip of the acetabulum. No crepitus or other signs of fracture could be detected. Reduction was performed and the patient was put to bed. After ample time for repair of the injured structures he was permitted to get up. But on attempting to walk there was considerable pain. Therefore a skiagram was taken. It showed an impacted fracture of the neck of the femur. The moral of these cases is obvious. An apparently slight injury of the hip should not be regarded as trivial. Examination under anæsthesia cannot be depended on, and if sufficient force is used to elicit crepitus in cases of impacted fracture the result may be disastrous. In all doubtful cases a skiagram should be taken.

A DEFINITION OF "IMPOSTOR."

OUR Australian correspondent sends us an account of a recent county-court action in which the judge supported a medical man by good law and sound common-sense. It was a case in which the plaintiff, a "surgical bootmaker," named Muir, sued Mr. W. Kent Hughes, a well-known surgeon of Melbourne, for £49 damages for alleged libel. The alleged libel was contained in a letter which Mr. Hughes wrote to a gentleman who was interesting himself in the treatment of a club-footed boy. Mr. Hughes having been asked to see the boy and informed that a subscription was being made to obtain surgical advice, said that he could not take fees raised by public subscription and offered to treat the boy at the Children's Hospital. The boy attended at the hospital but his relatives declined the operative treatment advised and removed him. Subsequently Mr. Hughes was asked to subscribe to a fund being raised to enable the boy to be treated in another way. In his reply he wrote: "The money, I understand, is being given to an impostor who poses as a foot specialist. I think you have let your philanthropic motives run away with your reason." The trial was concluded recently and Judge Johnston subsequently delivered his reserved judgment in which he found for the defendant on the plea of justification. The judgment contained a most admirable review of the facts adduced in evidence. *Inter alia* his honour said: "I have to decide whether on these facts defendant's letter was a libel on the plaintiff. Mr. McArthur for the defendant has pressed strongly for a finding that the plaintiff is an impostor in the sense that he is a dishonest man. He either knew or ought to have known the consequences of his acts. He has sailed perilously close to the wind. I believe he was conscious of the fact that he had limitations, for there was evidence to corroborate his statement that when he really believed an operation was necessary he suggested that a surgeon should be called in. But I am not satisfied that he was guilty of intentional fraud. Blinded by vanity and biassed in favour of his own methods, he deceived himself, with the result that he imposed on the public. I think, therefore, that the use of the word 'impostor' was justifiable. The word is simply the Latin form of those homely words 'put upon.' I think that suffering members of the public are very much 'put upon' if methods of this kind are to be permitted, and I believe that in this sense the defendant or any other member of the public renders a duty to his fellow members by publishing language which has the effect of characterising such methods even in harsh terms as 'an imposture.'".

COMPLIMENTARY DINNER TO SIR W. WATSON CHEYNE.

THE *students* (present and past) of King's College Hospital have arranged to give a complimentary dinner to Sir W. Watson Cheyne, to congratulate him on the well-merited baronetcy recently bestowed on him. The dinner will take place at the Waldorf Hotel, London, on Friday, July 17th, at 7 for 7.30 P.M. Old King's men have been communicated with as far as possible, but any of them who have not received notices are especially requested to communicate with the secretary of the dinner committee at the hospital. Owing to the large number of acceptances already received it has been found necessary to limit the invitation to old members of King's (staff or students).

NEURITIS OF THE MUSCULO-CUTANEOUS NERVE FROM RUPTURE OF THE BICEPS.

IN the *Journal of the American Medical Association* of May 16th Dr. P. S. Doane has reported an unusual injury and its result—neuritis of the musculo-cutaneous nerve from rupture of the biceps. A builder, aged 55 years, while on a ladder 20 feet from the ground fell. He broke his fall by grasping a projecting beam with the right hand and immediately felt a sharp pain in the right arm. The arm became swollen, but little attention was given to the injury until after the tenth day when intense pain began in the arm. This grew progressively worse and was so intense as to prevent sleep. With some difficulty he could sign cheques and letters. He consulted a physician who used an electric current for one month to relieve the pain without result. The patient was then seen by Dr. Doane who found just above the bend of the elbow on the inner side of the arm a globular mass about five centimetres in diameter, moveable in all directions to a moderate extent but less so downwards. Above it was a marked depression. The mass was thought to be muscular tissue and part of, if not all, the biceps. It was not tender but immediately above it and to its outer aspect was marked tenderness. On the outer side of the forearm there was some anæsthesia. The grip was weak and the arm could not be abducted beyond 45°. Neuritis of the musculo-cutaneous nerve secondary to rupture of the biceps, which it supplies, was diagnosed. As the general condition of the patient was not good an operation was not performed. To relieve the neuritis a bandage was applied below the ruptured muscle which was thus held up to a considerable extent. The arm was bandaged to the trunk so as to relax the muscle and to keep it motionless. After two months the neuritis had disappeared. Examination showed definitely rupture of the long head of the biceps but the condition of the short head could not be determined. The following operation was performed. An incision was made from the lower border of insertion of the pectoralis major downwards for three inches. Dissection showed that the long head of the biceps had been torn from its attachment to the upper border of the glenoid fossa and that contraction had invaginated it into the belly of the muscle. Not finding it possible to replace the long head in its original position Dr. Doane dissected it free from its invagination and adhesions, split the sheath of the short head, freshened the tendon surface of the long head, planted the latter into the short head, and sutured it there with interrupted catgut sutures. The wound was closed and the arm was kept in a flexed position for three weeks by a supporting plaster cast, after which a sling was used. Almost normal use of the arm was regained.

FORESTS AND FAMINE IN INDIA.

A FEW weeks ago there appeared in these columns a note upon the question of afforestation. It was discussed from the point of view of the influence of trees upon climate. If that question is of importance in this country the maintenance and cultivation of forest trees would seem to be of much greater importance to the welfare of the Indian peoples. The subject is ably discussed by Mr. J. Nisbet, formerly a conservator of forests at Burma, in the current number of the *Nineteenth Century*. He points out that the prosperity of India as an agricultural country depends mainly upon the rainfall. Any irregularity in the monsoon currents profoundly affects the crops where their thriving depends solely upon rainfall. Although much has latterly been done by irrigation and the construction of water-tanks there are vast tracts which have to depend entirely on the actual rainfall. Of late years the Government of India has been endeavouring not only to cope with want and famine but to eradicate the causes which bring about these disasters. So long ago as 1846 it was pointed out that in Bombay unrestrained clearances of forest had diminished the fertility of neighbouring gardens and rice lands. Thus the cutting down of trees in the South Konkan caused the springs to dry on the uplands and made the climate drier, the seasons more uncertain, and the land less fertile. In effect a forest acts as a sponge, and when the rain does fall water which would otherwise flow rapidly away is held up and distributed gradually to the adjoining rivers. But apart from this, Mr. Nisbet points out that in time of famine the forest can be thrown open to the villagers and their cattle. An Indian forest produces a number of edible roots and fruits, while the value of the forest as a grazing ground for cattle may be gauged from the fact that during the famine of 1897 nearly 700,000 head of cattle were saved by being turned into the forests of the Deccan. Mr. Nisbet's object in writing this article is to show that, apart from the value of the timber produced, the Indian Government would be well advised to extend the principle of afforestation in the interests of the public health.

POST-OPERATIVE DUODENAL ILEUS.

Professor Leopold Landau, speaking before the Berlin Medical Society, recently discussed the question of duodenal ileus. He said that, notwithstanding the strictest asepsis, peritonitis and ileus still develop sometimes after laparotomy, and it may be difficult to say which part of the intestine is occluded. Lately a good deal of light has been thrown on the matter by the statement of Professor Schnitzler of Vienna that ileus may be produced by strangulation of the duodenum by the superior mesenteric artery which runs behind the pancreas and in front of the duodenum to the root of the mesentery. The symptoms of duodenal ileus are very characteristic and may be met by a very simple proceeding. Professor Landau described the case of a woman upon whom a hysterectomy had been performed for myoma and who three days after the operation suffered from severe collapse, with a thready pulse of 160, stenocardia, and profuse bilious but not fæculent vomiting. There was pronounced meteorism and her state very much resembled acute peritonitis. The stomach-pump gave no relief, so by the advice of Professor Schnitzler she was placed in the abdominal position. Improvement took place almost immediately; an enormous quantity of flatus was discharged by the mouth and rectum, the meteorism disappeared, the pulse became normal, and the patient's comfort was restored. Professor Landau considers the development of duodenal ileus to be favoured by the fact that the duodenum is empty after operations and is therefore easily compressible. He recommends that the bowels should not be moved too vigorously and that the patient should be allowed out of bed as early as possible, even on the second or fourth day after the operation.

COMMEMORATION DAY AT LIVINGSTONE COLLEGE.

COMMEMORATION Day at Livingstone College was held on June 29th in the College buildings at Leyton, Essex, when Sir Patrick Manson, K.C.M.G., F.R.S., delivered an address on "The Importance of Knowledge of Tropical Medicine by Missionaries, especially in View of Recent Discoveries." Additional interest was added to the proceedings by reason of the fact that advantage was taken of the meeting of the Pan-Anglican Congress to invite the episcopal members of the Congress to a reception which was largely attended. The bishops were officially welcomed by the principal of the College, Dr. C. F. Harford, who in a short address pointed out that the College existed primarily to safeguard the health and the lives of missionaries. The Bishop of St. Albans, after joining in the welcome to the bishops, said that the work of Livingstone College was of the greatest utility. From his own experience of the tropics, now nearly 30 years ago, he considered it absolutely necessary that those living in India should have an elementary knowledge of medicine. Sir Patrick Manson, in the course of a very able address, summarised the present-day knowledge of tropical diseases and expressed the opinion in which everyone will concur that those who send out missionaries to work in foreign lands should lay to heart the importance of a knowledge of tropical diseases to a missionary. It was not fair, he said, to anyone to ask a man to go abroad and to face avoidable risks. Martyrdom was one thing, suicide was another, and *murder*, though he did not like to say the word, was a third, yet to send a man abroad to work as a missionary in unhealthy climates and not provide him with proper information as to how to prevent himself being killed—he left his hearers to say what that would be. People had not yet come to recognise; this they would, he thought, by and by. The remedy depended upon the public. The public should demand that such a state of affairs *should be impossible*, whether in missionary or Government circles. Livingstone College, which deals with the special needs of missionaries of widely differing schools of thought, is to be congratulated upon its useful work.

SOME RECENT WORK ON PARASITIC WORMS.

Dr. C. Wardell Stiles and Dr. Joseph Goldberger have recently published a series of papers dealing with parasitic worms.[1] A very peculiar case of parasitism in man was observed in Florida. The worms, which live in the subcutaneous tissue and cause swelling resembling acne, have been determined as very closely related to, and perhaps identical with, Sparganum proliferum. This parasite has been reported on only one former occasion, when it was found in Japan, but its life-history, source of infection, prevention, and treatment are still unknown. Its chief peculiarity is a reproduction in its larval stage by the formation of supernumerary heads, which may become independent and wander through the tissue. In another paper the original specimen of Filaria restiformis is described. It has hitherto been thought to be a parasite from man, but it proves to be an immature horse-hair worm and it is exceedingly doubtful whether it is a parasite of man. In a further paper two new species of trematode are described, Homalogaster philippinensis, collected from the cæcum of cattle in the Philippines, and Agamodistomum nanus, an agamic encysted species collected from the partridge in West Africa. It is not known whether the latter parasite is transmissible to man. The last paper deals with a re-examination of the original specimen of a tapeworm which Weinland described as Tænia solium, var. abietina. Opinions have differed in regard to the exact nature of this parasite, some writers considering that it represented a distinct species, while others held that it was a variety of Tænia solium or of Tænia saginata. The original specimen, consisting of a few segments, is in poor condition, precluding a final judgment as to its exact systematic position. It appears to be a dwarfed specimen of Tænia saginata, of which it is possibly a subspecies. The Bulletin concludes with a magnificent series of illustrations of these parasites, showing their macroscopical and microscopical characters.

TREATMENT OF TUBERCULOSIS OF THE KIDNEY.

BEFORE the Verein für Innere Medicin of Berlin Professor Casper read a paper recently on the treatment of tuberculosis of the kidney. He uttered a warning against tuberculin injections of which the results are uncertain. He considered that nephrectomy was still the best method and stated that out of 42 cases operated upon in that way only five patients had died. The decrease of mortality was due to improved methods of diagnosis; the old method of palpation was not trustworthy but cystoscopy and catheterisation of the ureters in the great majority of cases have made the diagnosis of the functional powers of the kidneys quite certain. But even if neither of these methods were available in order to ascertain if the second kidney were sound, Professor Casper recommended that after exposing the diseased kidney, and before removing it, the ureter should be compressed so that urine should only flow into the bladder from the organ presumed to be healthy. The urine should be drawn off and examined and if it were found to be normal a nephrectomy of the tuberculous kidney might be performed without risk.

UNWHOLESOME MEAT IN RURAL DISTRICTS.

WE have on numerous occasions had reason to call attention to the difficulty which exists in controlling or preventing the sale of unwholesome meat in rural districts, and there can, we imagine, be no question that a considerable amount of the unwholesome meat consigned to our large towns reaches them through the lack of adequate control in rural districts. It is therefore a matter for congratulation to find that in East Sussex considerable vigilance in the matter of meat control is exercised and, as will have been seen from a letter from Mr. Hugh Stott in our correspondence columns of June 27th, the Cuckfield rural district council has recently taken action against a cattle-dealer for slaughtering an animal on unlicensed premises. The defendant, as is so frequently the case, endeavoured to evade justice by raising a technical quibble to the effect that there had been some omission in the process of conferring urban powers upon the rural district council and the bench, misled by the counsel's pleading, dismissed the case. Fortunately, the district council had the courage to appeal against the decision and it was rewarded by the technical point being quashed by the Lord Chief Justice who ruled that it was no more necessary to prove the publication of an Order made 26 years ago than it was necessary for the defendant to prove that no such Order had been made. On the case being further heard before the Haywards Heath bench the defendant was fined £1 and £5 10*s*. 2*d*. costs. We are very glad to see this decision and the district council in question is cordially to be congratulated upon having appealed. The Haywards Heath bench seems determined to protect the public health, and in the case of a butcher charged with exposing meat for sale in an advanced stage of tuberculosis, this bench, although the butcher had a good record, fined the defendant £50 and 5 guineas costs. There is a wholesome ring about this judgment and it looks as if the work of the Royal Commission on Tuberculosis is at last bearing fruit.

THE DISCOVERY OF THE THERAPEUTIC VALUE OF DIGITALIS BY WILLIAM WITHERINGTON.

In the *Pharmaceutical Journal* of May 23rd Dr. J. Gordon Sharp contributes an article on the *history of foxglove*, a drug which, although used as an external application to sores and ulcers in Saxon times, was not greatly employed internally until about 1775, when Dr. William Witherington discovered its true action. This well-known botanist and therapeutist had observed that country people often cured themselves of dropsy by drinking foxglove tea. He experimented with preparations of the plant and soon found that the success of the drug was due to its diuretic action and not to its purgative or nauseating properties. He afterwards published a book on digitalis[1] and was instrumental in establishing for the drug a reputation so great that it was recognised in the Edinburgh Pharmacopœia of 1783 in the form of an infusion. This preparation, which has been held in high esteem by many clinicians, was really a freshly made weak tincture prepared by macerating one drachm of the dried leaves in eight ounces of boiling water and an ounce of spirit of cinnamon for four hours. It is probable that this so-called infusion contained a larger proportion of the glucosidal constituents of digitalis than is the case with the aqueous infusion which later came into vogue. As hot water dissolves only a trifling proportion of some of the glucosides present in the leaves it would seem that the change was a mistake. Dr. Witherington himself appears to have used only the dried leaves or an aqueous infusion, to which was subsequently added spirit of cinnamon as a preservative. The tincture, however, soon came into use and was included in the pharmacopœias that were issued at the beginning of the nineteenth century. Dr. Witherington's chief work consisted in establishing digitalis on a firm therapeutic basis from which it has never been displaced. The following quotation from his work shows how clearly he understood the action of the drug: "It has a power over the motion of the heart to a degree yet unobserved in any other medicine ...... It seldom succeeds in men ...... of tense fibre, or in those with a tight and cordy pulse. On the contrary, if the pulse be feeble or intermitting, the countenance pale, the lips livid, the skin cold, the swollen belly soft and fluctuating, or the anasarcous limbs pitting readily under the pressure of the finger, we may expect the diuretic effects to follow in a kindly manner." In other words, Dr. Witherington recognised the unsuitableness of digitalis in cases of high tension, but he was aware of its value when the arterial tension was low.

THE Royal Waterloo Hospital for Children and Women is acknowledging the receipt of the munificent gift of £13,105 (the interest on which only can be used) from a donor who wishes to remain anonymous. The most hearty thanks are due from the authorities of the charity for this splendid donation which will considerably lighten their responsibilities at a time when funds are very urgently needed.

IN our last issue we announced that in connexion with the approaching visit to England of French medical men Professor Landouzy would lecture at 20, Hanover-square, London, on July 14th. We now hear with regret that urgent official business will prevent the eminent *savant* from fulfilling this engagement.

THE dinner to members of the Voyages d'Études Médicales will take place at the Hotel Cecil on Thursday, July 16th, at 7.30 P.M., when Dr. George Ogilvie will occupy the chair.

A VISIT TO PROFESSOR WERTHEIM'S CLINIQUE IN VIENNA.

BY ARTHUR H. N. LEWERS, M.D. LOND., F.R.C.P. LOND.,
SENIOR OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

A BELIEF, from all I had read and heard of it, that the more extended operation devised by Professor Wertheim for cases of cancer of the cervix—familiarly known as Wertheim's hysterectomy—is destined to become *the* operation in cases of this kind, which are operable at at all, led me to ask him to give me the opportunity of seeing him perform the operation in the Kaiserin Elisabeth Hospital in Vienna, where his hospital work is carried on. In the kindest way Professor Wertheim arranged to keep three cases of cancer of the cervix for my visit, and I saw him operate on them on three consecutive days—June 9th, 10th, and 11th. He also gave me an opportunity of examining the cases before the operation. The preliminary curetting and cauterising of the growth was done in each case immediately before the operation, and without an anæsthetic. So far as I could judge the patients did not seem to experience any very severe pain. The object of dispensing with an anæsthetic for this preliminary step is to shorten as much as possible the duration of the chloroform narcosis. After the curetting the patient was removed into another operating theatre, and prepared for laparotomy in the usual way. In each of the cases I saw the operation was conducted in the Trendelenburg position, the pelvis being raised to a moderate extent only. In the first and the third cases the patient was under the influence of a general anæsthetic (Billroth's mixture) for the whole of the abdominal operation. In the second case spinal anæsthesia was employed for the first half hour of the operation, after which, as the anæsthetic effect seemed to be wearing off, a general anæsthetic was administered. The first case was a fairly favourable one as regards the degree of advancement of the disease. In it there was some slight "thickening" to the left of the cervix suggesting some extension of the growth into the connective tissue there. I should have regarded the case as too far advanced for vaginal hysterectomy. The third was a very favourable case, the disease being at quite an early stage, requiring the microscope to confirm the diagnosis. In cases such as these I understand Professor Wertheim uses general anæsthesia. The second case, that operated on on June 10th, was about as unfavourable a case as it would be possible to have short of one completely inoperable. The uterus was fixed, and there was a large malignant chasm in the situation of the cervix, the lower edge of which was a long way down on the posterior vaginal wall. The growth seemed to have involved the rectum and bladder. Professor Wertheim himself regarded this case as one in which it was very doubtful if the operation could be performed; at all events, the case was evidently one in which, if the operation were possible, the difficulties would reach a maximum, and the duration of the operation be correspondingly increased. For cases of this kind spinal anæsthesia is employed to shorten the time during which the patient must remain under the influence of a general anæsthetic. It may be added that this case proved to be one of extreme difficulty, necessitating opening the bladder, and an extensive and deep dissection of the posterior vaginal wall from the rectum. The operation was, however, satisfactorily completed, and the whole of the diseased tissue seemed (from a subsequent examination of the specimen) to have been completely removed. In spite of the advanced stage of the disease in this case no enlarged glands were found. In contrast to this it may be mentioned that in the first case, that operated on on June 9th, although, as far as it could be ascertained by examination, the disease was not nearly so advanced as in that just described, an enlarged gland was found on the iliac vessels and removed. On microscopical examination it proved to be infiltrated with cancer. Vaginal hysterectomy in this case would obviously have been useless.

---

[1] *An Account of the Foxglove and Some of its Medical Uses, with Practical Remarks on Dropsy and Other Diseases.* By William Witherington, M.D. London: G. G. J. and J. Robinson. 1785.

The rapidity with which all three operations were completed was very noticeable, and the amount of the bleeding was very slight. Sponging in consequence was quite infrequent. The condition of each of the patients at the conclusion of the operation was also very satisfactory. As regards the first two cases (the second being the extremely difficult case), I saw the patients two days and one day after the operation respectively, and they seemed as well as after a simple ovariotomy.

Professor Wertheim told me that he has now completed more than 500 of the operations under consideration. He has arranged them in groups of 30. In the first 30 cases the mortality exceeded 40 per cent., while in the last 30 it is in the neighbourhood of 7 per cent. At first the operation was restricted to cases too far advanced for vaginal hysterectomy; but the later groups comprise all cases of cancer of the cervix operated on. As regards the after-history, Professor Wertheim has 60 per cent. of his cases free from recurrence after five years. In this calculation I understand that the cases dying from the operation are omitted, and it is to be taken as meaning that of those who recovered from the operation nearly two-thirds are free from recurrence after five years.

The reduction in the mortality in the more recent series is very remarkable. No doubt it is chiefly to be attributed to an improvement in the technique of the operation resulting from so large an experience; partly also to the partial use of spinal anæsthesia in cases where great difficulties are expected. To a less extent it is also to be accounted for by the fact that in the later series the extended operation has been employed for all cases operated on at all; that it has been employed for the early cases in which the operation is so much less difficult and correspondingly less dangerous as well as for the more advanced. The after-results are certainly much more favourable than many English gynæcologists would have been prepared to expect. Even omitting those that died from the operation 60 per cent. of those who survived it free from recurrence after five years makes a very satisfactory record. I had the opportunity of examining two cases that had been operated on some considerable time previously, who had come up to report themselves in the ordinary course. One of these had been operated on more than four years ago: this was a case in which the glands had been affected. The patient was quite well, and no sign of recurrence could be found on examination. The other patient had been operated on more recently, rather less than two years ago; she also was quite well.

The introduction of Wertheim's operation, which renders many relatively advanced and, indeed, some actually very advanced cases of cancer of the cervix operable, should, however, cause no relaxation in our efforts to get cases to seek advice while the disease is in an early stage. The earlier the stage of the disease, the less the mortality of the operation, and the better the prospect as regards after-results. In carefully selected early cases there is no doubt that vaginal hysterectomy, or even the supra-vaginal amputation of the cervix, has been attended with good results as regards the after-history. I have had many cases illustrating this in my own practice. But, even in this class of case, it must obviously be an advantage to make the lines of section employed in removing the diseased tissues as far as possible from the growth, and in Wertheim's operation there is a very much larger margin between these lines of section and the growth than it is possible to obtain in vaginal hysterectomy. The latter operation will, I feel sure, be gradually restricted to those cases in which Wertheim's operation is contra-indicated, as, for instance, in patients over 60 years of age, or in those who are otherwise unfavourable subjects for a severe operation. The fact that Professor Wertheim has been able to reduce his mortality from over 40 per cent. to 7 per cent. cannot fail to encourage those of us here who are already performing the operation, and must surely induce those gynæcologists who have not yet performed it to recognise it as having taken its place among standard gynæcological operations.

THE LIERNUR PNEUMATIC SEWERAGE SYSTEM.

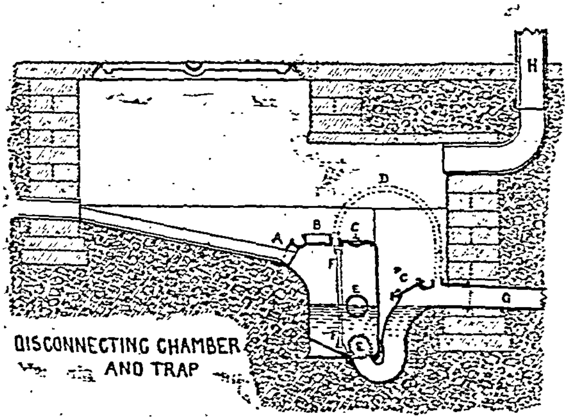
The scheme forming the subject of the present notice was first introduced on the continent by the inventors, Messrs. F. and W. Liernur, some 30 years ago, when it was applied to the city of Amsterdam, yet notwithstanding that we justly pride ourselves on taking a leading position in all sanitary questions, there has been but one installation of this system established in this country up to the present—viz., at Stansted in Essex. In 1903 the local sanitary authorities of Stansted contemplated laying down a system of drainage for their district; the Liernur plan was submitted to them and it seemed to offer the best solution of the difficulties which they had to encounter. The council, however, hesitated to adopt a system which in England had never been put to a practical test. The English Syndicate of the Liernur Company had such confidence in the capabilities of their patent that they offered to make the installation, and in the event of failure to remove it at the end of three years, themselves bearing all expenses. This offer was accepted, and it was not until 1906 that the district council applied for and obtained from the Local Government Board a grant of money to enable it to repay the Liernur Syndicate for their enterprising venture. In arriving at their decision the inspectors of the Local Government Board, Mr. A. A. G. Malet, M.Inst.C.E., and Dr. L. W. Darra Mair, were assisted by the favourable evidence given, amongst others, by Dr. J. C. Thresh, medical officer of health of the county of Essex, and Dr. R. A. Dunn, medical officer of health of the East Herts and West Essex combined district.

The Liernur system is an alternative to that known as the Shone and Ault ejector system for overcoming the difficulties experienced in draining a low level district. Indeed, it is more than that: it is a threatened revolution in existing sanitary procedure. In the Shone system compressed air is introduced automatically into a series of ejection chambers placed in the main drain, by which means the sewage is forced to the higher level at the outfall. In the Liernur system a vacuum is created at the outfall of the main drain and the pressure of the atmosphere at the other extremity forces the contents to that point. Notwithstanding that there are two or three points which may be open to criticism, there are advantages offered by this system of unquestionable value from a hygienic and also from an economic standpoint—some of which are as follows. 1. The ability thoroughly to free the sewers from all deposit and foul air as often as the vacuum is applied. 2. The avoidance of polluting the streets with contaminated air escaping from the road gratings, ventilating pipes, and manholes, as is at present the case. 3. The reduction of the risk of contaminating the ground by leakage from defective sewers; the probability, amounting almost to a certainty, being that any defect in the pneumatic sewer would at once be detected through the vacuum being destroyed by the admission of air. 4. The avoidance of the necessity of laying the sewer at a lower level than the lowest point to be drained for the purpose of acquiring a fall. This has been proved at Trouville where the 10-inch main sewer extends for over two miles at one dead level. 5. The avoidance of a waste of water for flushing purposes. 6. The reduction in the cost of construction and maintenance.

In addition to a saving in the cost of construction, economy in working arises from the fact that at the pumping station the quantity of sewage received is kept to the lowest possible limit, and this is effected without in any way restricting the use of water for flushing closets, sinks, &c., or giving rise to any nuisance. Stoppages in the sewers may be said to be impossible. There can be no doubt that the fact of the sewage being more uniform in quality (owing to the exclusion of rain water) and being broken up by the violence of its passage through the small sewers facilitates its purification by bacterial treatment and also enhances its value when applied to purposes of irrigation.

It would almost seem from the reluctance of most people to accept any new departure from long-established customs that the delay must originate in some natural law "that makes us rather bear the ills we have than fly to others that we know not of." Or can it be that some find it less trouble to accept things as they are than to exert themselves to grasp the details of any fresh proposition in order to judge it on its merits? Or possibly vested interests act as a strong factor against any innovation. To whatever cause, however, we may attribute the delay in the more general adoption of a system which has much to recommend it, both on the grounds of sanitary efficiency and economy, signs are not wanting of an awaking interest on the part of various municipal authorities for whom schemes are being prepared.

FIG. 1.



Section. Trap in position in disconnecting chamber.

A short reference to the Liernur patent appeared in THE LANCET of August 12th, 1899, p. 420, in an article on Sewage Disposal, but a more detailed account of it and of the works at Stansted, which were recently visited by our Commissioner, may interest many of our readers. Some descriptions of the plant used, with an account of the method of working, will readily enable them with the aid of the illustrations to grasp the very simple details. In the first place, though it is somewhat revolutionary in character, the only alteration necessary in the house drains is the substitution of a special container and trap (Fig. 1) for the syphon trap between the house and the sewer already in common use. It is also imperative that the house drains shall be properly ventilated, especial care being given to the traps of the water closets. The interceptor trap answers a two-fold purpose. It disconnects the house drains from the sewers while it protects the traps and offers a sufficient resistance to permit the vacuum to reach the necessary depression of half an atmosphere before it comes into action. It also forms a screen to hold back such unconsidered trifles as dead cats, discarded apparel, empty preserved-food tins, and other items which a free-handed public would sometimes commit to the seclusion of the sewers. Figs. 1 and 1A show the trap in the position which it would occupy in an ordinary disconnecting chamber. On the continent it is used independently, the chamber being dispensed with. Unlike so many things in which our neighbours across the Channel excel, domestic sanitary procedure forms somewhat an exception. For instance, it is not considered wrong to place this disconnecting chamber inside the houses, accompanied by the drains and soil-pipe. It is true that in the heart of the City of London at times the same thing has to be done but only under exceptional conditions. Placed externally in connexion with the vacuum system it is unobjectionable, though not adapted to gravitation drainage. The trap is like an oblong gully trap with a deep syphon to resist the pull of the vacuum. It is 15 inches long, 10 inches wide, and 24 inches deep. Its normal contents are seven or eight gallons. A is the main inlet from the drain. This on the continent is connected directly to the drain without any open channel. For use in a disconnecting chamber this socket should have a less acute angle with an internal lip at A to throw the liquid into the centre of the trap. B is a socket intended for the direct connexion of the soil and ventilating pipe and is unnecessary with a chamber. C, inspection eyes. D is a small air inlet or anti-syphonage pipe to relieve the trap, as in large installations a very slight depression is constantly maintained in the sewer to keep them ventilated during the intervals of the full application of the vacuum. The retention of this pipe is not, however, insisted upon. E is a hollow vulcanite ball which floats on the water and forms a seal for the protection of the house-traps against the vacuum after the extraction of the contents of the disconnecting trap. Immediately the vacuum ceases an amount of water sufficient to form a seal, previously held up in the long outlet arm, falls back into the trap and the ball again floats. F, metal rods forming the screen. G, outlet to sewer. H, fresh air inlet.

Plan of system at Stansted.

The village of Stansted, where the system can be seen in operation, contains some 2000 inhabitants, with an average daily consumption of 15 gallons of water per head. The village is a straggling one, placed partly on a hill of moderate elevation and partly in a hollow in which any efficient plan of sewerage by gravitation would be extremely difficult and costly. (See Fig. 2.) Two systems have therefore been installed, one on the high level on the gravitation principle and in the low-lying district the Liernur vacuum system. This last is connected with 150 houses, having a population of about 1000, two large schools, a factory employing 250 workers, and also with a brewery discharging about 25,000 gallons of waste water weekly. The sewage collected at the station of the lower works (B, Fig. 2) is pumped up into the high level sewer at C, from which it gravitates to the outfall. Here, after passing through a form of septic tank, it is sprinkled on to a coke filter, the effluent being passed on to the land. There is a separate system of surface drainage for carrying all storm water into the brook D.

Main drains.—In this district the houses not having basements no very deep digging was necessary on this account, but owing to some local obstructions the 5-inch cast-iron main sewer had to be kept 6 feet below the road surface and is laid almost on a dead level from end to end. In many cases it is sufficient to keep the drains 2 or 3 feet underground in order to escape frost. The branch sewers are of 4-inch iron pipe. Indeed, cast-iron pipes with caulked lead joints, each length being tested as laid, are used throughout. Experiments show that air in a pipe placed under a vacuum converges to the centre like the spokes of a wheel from the rim to the hub, consequently any dry matter adhering to the top and sides is at once forced off by the pressure of the air contained within it.

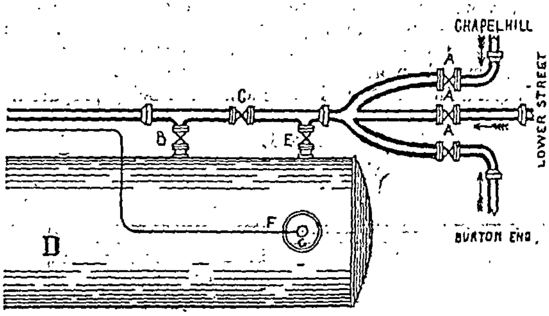
District cylinder.—There are three branch sewers converging to a point where the principal streets meet (see B on plan, Fig. 2). Here is placed a district cylinder (Fig. 3) to which they are connected through the 5-inch main sewer which also again acts as a by-pass leading to the sewage tank at the works. A valve (A) controls each of the branch sewers, three other valves (B, C, and E) being fitted to the 5-inch main to cut off the cylinder from the sewage tank while emptying the branch sewers into the cylinder. An air valve (G) placed on the top is opened whenever the vacuum is applied to empty the cylinder. This district cylinder is placed in a small chamber or station beneath the roadway, access to it being gained through a manhole. In the case of large towns such stations can be multiplied indefinitely. One district station suffices for every 2000 of the population. There are nine such stations at Trouville, where the vacuum system has been satisfactorily working for the past ten years, and here in the height of the season there is a population of from 30,000 to 40,000. Each district cylinder is connected by the main sewer to the central station. A vacuum pipe also follows the same course, being joined to the district cylinder under control of a valve which is kept closed excepting when the sewers are being cleared of their contents. In large installations a vacuum of half an atmosphere is constantly maintained in this pipe, but in a small village like Stansted this is unnecessary, the required depression being quickly obtained after starting the pumps; also the separate vacuum pipe is dispensed with, the main sewer answering the purpose, as shown in Fig. 3.

The central station.—This is fitted with a cylinder of about 2800 gallons capacity connected directly with the main sewer, which last, as already mentioned, also acts as a by-pass for the sewage to the storage tank. Two valves control the connexion of this sewer with the tank and the cylinder. This last is also fitted with a gauge and an inlet safety valve to open should the vacuum produced exceed half an atmosphere. Another gauge also indicates the quantity of sewage present. An air valve is placed on the top of the cylinders, which is opened to admit the air when emptying the same. There are two vacuum pumps of 4-h.p. each, worked by an 8-h.p. gas engine.

Storage tank.—Adjoining the engine-room is the sewage storage tank capable of holding 30,000 gallons, the estimated amount collected per diem being 10,000 gallons. Into this a considerable amount of the sewage finds its way directly by gravitation along the almost level main sewer, acting as a by-pass to the district cylinder. The whole of the sewage is finally collected in this tank from the cylinders and sewers by application of the vacuum. An ordinary force pump raises the contents of the storage tank through an iron rising main to the point C (Fig. 2), where it discharges into the high level system as already mentioned. Had it been possible to locate the central station at the outfall works of the high level system this storage tank and lift pump would have been unnecessary and a less powerful gas engine would have sufficed. The fire-box of a small inclosed furnace is connected to the sewage tank by a ventilating pipe from the same, and any gases generated in the tank with the air drawn from the sewers can be made to pass through the furnace.

The application of the vacuum and the process of emptying the sewerage system is extremely simple, occupying about ten minutes. At Stansted it is accomplished as follows. The operator at the district station (see Fig. 3) first closes the valve A on each of the three branch sewers and valves B and C on the main sewer, thus cutting the connexions between the cylinder D and the central station. The main sewer is then placed under vacuum by the engineer at the central station, after first closing the valve of the by-pass to the sewage tank. The man at the district station then opens valve F on the 2-inch branch vacuum-pipe leading off the main sewer, thus placing the cylinder under depression. All being in readiness the valve A is opened on the first branch sewer. At once the atmospheric air rushes down the soil or ventilating pipes of the houses connected to this particular branch, when its contents and the accumulations in the disconnecting traps (Fig. 1) are forced into the cylinder through E at the rate of 12 or more feet per second by the pressure of the extra half atmosphere behind. In this case the pipes being only 4 inches (roughly 12½ inches sectional area) the compelling force in the pipes would equal about 94 pounds which would increase with the momentum of the moving mass, while the resistance in front, owing to the expansion of the air of the drains in the vacuum toward which it rushed, would diminish. As a matter of fact, the superficial area exposed on the surface of the trap (Fig. 1) being much larger than that of the 4-inch pipe, a greater atmospheric force would at first be exerted and help to overcome the inertia of the mass of soil, &c., present in it. The first sewer being cleared, the valve A is closed and the operation is repeated in the case of the other branch sewers. The contents of all three being now in the district cylinder and the sewers themselves cut off from it valve B is next opened establishing the connexion between the district and central cylinders, while valve F on the branch vacuum-pipe is closed. By now opening the air valve G in the district cylinder the whole of its contents are at once shot through the main sewer into the one at the central station to be afterwards discharged into the sewage tank and from there pumped into the high level sewer as already stated. The several valves are now opened or closed as necessary to restore normal conditions. The noise made by the air rushing through the valve into the cylinder helps the observer in a measure to realise the force exerted which is such that a newspaper held at the valve opening is instantly sucked into the cylinder and torn from the hand. The operation is slightly more complicated than in the case where there is a separate vacuum pipe and when a vacuum is always maintained in the main sewer and the sewage tank is omitted.

FIG. 3.



District cylinder.

Messrs. Liernur's system is one that makes a strong appeal on hygienic grounds, and for low-lying districts, such as river valleys and shore levels, should prove of great value. Of course, in time of flood it would be as helpless as any other until the water subsided to the ground surface. After this, unlike ordinary deep-laid brick and stoneware gravitation sewers which often remain waterlogged for days until the flood has fallen below their own level, the water not being able to gain an entrance to the air-tight pipes normal conditions would quickly be restored. The patentees avoid so far as possible the admission of storm waters to their sewers on the grounds that it is foolish to foul comparatively clean water by mixing it with sewage, afterwards having the expense of purifying it. Also that the water is not wanted for flushing their sewers. If included, an increased cost for pumping is incurred and, of course, larger mains must be laid.

SANITATION IN INDIA.

A NOTE ON THE SANITARY ORGANISATION OF THE ARMY IN INDIA.

IN THE LANCET of Feb. 22nd a series of articles was commenced dealing with Sanitary Reform in India. These articles give an account of sanitary administration in that dependency, while the following article gives a lucid description of the sanitary organisation of the army in India and comes from the pen of one of our correspondents in that country.

In recent years many important changes have been effected which bring the sanitary organisation of the troops serving in India, both British and native, into a state of high efficiency. The sanitary administration of the army as it stands to-day will not only compare most favourably with the various municipal public health organisations in the towns of the United Kingdom but is perhaps closely approached only by that of Japan and to a lesser extent by the German army. In proof of this assertion attention is invited to a comparison of the health statistics of the British army for the years 1906-07 with those of the previous 25 years, or a comparison of these again with similar statistics of foreign armies. These figures show very striking evidence, as do the health statistics of the army of India for the past ten years, which prove that the drop in the hospital admission ratio for all kinds of preventable diseases is very remarkable.

The factors in army sanitary administration which have brought about these changes have taken nearly ten years in their evolution. The foundation-stone of scientific sanitation in India may be said to have been laid when in 1899 Surgeon-General Sir William Taylor, K.C.B., as principal medical officer to His Majesty's forces in India, first recognised the importance of appointing a specially qualified medical officer of health as sanitary adviser on his staff. In previous years the successive principal medical officers of India controlled the sanitation of the army without expert advice. Sir William Taylor selected as his sanitary adviser on the headquarters staff Lieutenant-Colonel A. M. Davies, R.A.M.C., a diplomate in public health, now professor in military sanitation at the Royal Army Medical College in London. The next progressive step in the advance of sanitary science was taken by Surgeon-General Sir Thomas Gallwey, K.C.M.G., C.B., on his appointment as principal medical officer on Lord Kitchener's staff in India in 1902, when he obtained the sanction of the Government of India to extend the system of medical officers of health to each of the Presidency commands; on this being granted he selected specially qualified officers from the Royal Army Medical Corps, a *sine quâ non* for these appointments being the possession of the D.P.H. These military medical officers of health were placed on the staff of the principal medical officer of each of the commands—Bengal, Madras, Bombay, and Punjab—and their respective areas were divided into districts. Well-equipped bacteriological laboratories were initiated for each district, which were placed in charge of specially selected medical officers either possessing an Army Council qualification in bacteriology or preventive medicine or a diploma in public health. Much of the research work which has led to the reduction of malarial and other fevers in India has been carried out in these laboratories.

On the appointment of Surgeon-General W. L. Gubbins, C.B., M.V.O., as principal medical officer of India in 1906, sanitary science received a still further stimulus, the first progressive step being the increase in numbers of the district laboratories which were doing such good work and the next the increase in the staff of each from one medical officer to two, one from the Royal Army Medical Corps and one from the Indian Medical Service. When Lord Kitchener abolished the Presidency commands and created independent divisional commanders in 1907, Surgeon-General Gubbins, recognising the opportunity for the still further improvement of preventive medicine in India, at once obtained sanction from the Government for the appointment of a medical officer of health to each of the ten divisions of the army, a progressive step which has already proved of great benefit to the army. It will be seen from this brief retrospect that the chain of sanitary administration in the Indian army has been forged link by link.

Passing on to consider the executive *personnel* and the distribution of work under the present sanitary system, we find that the Commander-in-Chief holds the principal medical officer on his staff at army headquarters, Simla, responsible for the health of the army. Under that important officer's direct orders all instructions affecting the general health and sanitation of the army as a whole are issued to general officers commanding divisions. The sanitary executive, however, in so far as it affects such conservancy as is under cantonment magistrates of military stations, belongs to the cantonment magistrates' department which is administered by the quartermaster-general in India, whose department forms a separate division of the army headquarters staff in Simla. The principal medical officer's division is divided into sections, one of which is under the immediate supervision of a medical officer of health (sanitary officer, army headquarters), who examines and reports on all the sanitary work of the entire army, including all plans of new buildings, sites of new cantonments, &c., these being submitted to the principal medical officer for medical approval by the great departments concerned (Quartermaster-General and Military Works). Expert sanitary advice or criticism, as the case may be, is offered by the sanitary officer on these files before they are laid before the principal medical officer. Similarly general questions affecting the clothing, rations, and water-supplies of the army all pass through the hands of the sanitary officer before receiving endorsement and final approval of the Commander-in-Chief. All hygienic measures and all general questions concerning the prevention of disease as distinguished from treatment, such as vaccination and antityphoid inoculation, as well as epidemiological investigation, instruction classes in sanitation, reports and returns connected with sanitation, and also arrangements for sanitary inspections generally, as, for instance, those connected with outbreaks of epidemic disease, special supervision of biological installations (sewage tanks), and disinfectors, are under the control of the sanitary officer, who also carries out the headquarter analysis of spirits, wines, medical comforts, and such-like things.

In conformity with the model of procedure at army headquarters the principal medical officer of each division, who is on the staff of the general officer commanding, is held responsible by the latter for the health and proper sanitary arrangements connected with the troops in his divisional area. Each divisional principal medical officer's division is divided into sections, one of which, the sanitary section, is under the immediate supervision of a medical officer of health (divisional sanitary officer). This officer holds practically the same position as a medical officer of health in the United Kingdom and his duties are similar to those already described as laid down for the sanitary officer army headquarters, except that he comes much more closely into touch with the executive side of sanitary work in his divisional area and is more especially concerned in taking immediate sanitary steps on the occurrence of infectious or contagious disease, each case of which is notified to him. When epidemics occur it is his duty to investigate the cause of the outbreaks and to make such sanitary recommendations and to take such precautions as he may think advisable. Another most important duty of the divisional sanitary officer is that of keeping himself acquainted with the various systems of water-supplies in use not only in the stations of his divisional area but also in the various camping grounds scattered over the country which constitute some of the greatest sources of enteric or cholera infection to troops on manœuvres or route march. He has to analyse and to examine rations such as tea, sugar, flour, rice, &c., and for this purpose a well-equipped laboratory is provided at the headquarter station of each division. The divisional sanitary officers are generally assisted by other medical officers who are either detailed or else volunteer for this purpose. It may be noted that great benefit from an educational point of view is derived from these laboratories, as other medical officers, either those on duty at the head-quarter station or those on leave, take advantage of attending courses in bacteriology and tropical research work, since all investigations in clinical pathology required by the local hospitals are carried out in them and instruction is afforded in these matters to all who like to attend.

The next link in the chain of sanitary organisation, and perhaps the most important of the whole system, is the sanitary administration and executive of a military station or cantonment. Here we are met with the crux of the whole sanitary problem in India. Formerly cantonments were intended for troops only, with accommodation outside for their necessary followers and no others, but as time went on these cantonments became surrounded by bazaars which sprang up to shelter natives who make their living out of the soldier, and houses within cantonments passed into the hands of native landlords who have no idea of sanitary requirements and who cannot be induced to spend money on their property. The natives living in these surrounding bazaars are always in evidence and they contaminate the food and water which are required by the soldier. They only return to their hovels in the bazaar to sleep and may on coming back convey disease directly to barracks. The officer commanding a military cantonment or station is responsible for its sanitation and issues his orders connected therewith through the sanitary adviser on his staff—namely, the senior medical officer—to all concerned. The officers commanding units (regiments, batteries, corps, departments, and station hospitals) are held responsible for the areas occupied by the troops, followers, &c., under their command by the officer commanding the station, and such parts of cantonments which do not come under the above headings are in the sanitary charge of the cantonment magistrate. All these areas are periodically inspected as to their sanitary condition by the senior medical officer of the station. The sanitary executive or conservancy department (outside unit lines) is in charge of the cantonment magistrate and this officer is held responsible by the officer commanding the station that all night soil, excreta (both human and animal), refuse, rubbish, &c., are properly removed and disposed of outside cantonments. He has also the watering of roads in his charge. The sanitary condition of the trenching grounds for night soil, &c., is periodically inspected by the senior medical officer of the station and reported on by him.

Each unit (regiment, battery, &c.) in a station has a medical officer attached who is the sanitary adviser of the officer commanding, and this officer carries out frequent, in some cases daily, inspections of the lines and men under his immediate charge. Sanitary cadres exist in every unit, comprising a proportional number of men in charge of a non-commissioned officer whose sole duty is to go round barracks and to supervise the menial conservancy establishment (sweepers, and so on). The water-supply of stations and camping grounds as far as executive duties are concerned is under the Military Works Department; it is examined chemically under the orders of the senior medical officer at least twice a year (once before and once after the monsoon), and bacteriologically as often as may be thought necessary by the divisional sanitary officer. At all divisional and brigade head-quarters, as before stated, the laboratories carry out the clinical investigation of the station; besides this they carry out such research work as is beyond the power of the hospitals of other stations in their respective areas, and work beyond the scope of a brigade laboratory may be referred to the divisional laboratory. The brigade laboratories are inspected from time to time by the divisional sanitary officer and the divisional laboratories by the sanitary officer at army headquarters. High-power microscopes with oil immersion lenses and suitable reagents are issued to all stations for clinical, diagnostic, and research work. Every endeavour is made to aid all forms of microscopic investigations even in the smallest stations. Keen workers have only to ask for what they want and they are supplied with cultures and apparatus, on loan or otherwise, from divisional head-quarters. Most hospitals carry out their own Widal and blood examinations for enteric and other fevers.

With the memory of the conditions under which the pioneer work of Ronald Ross, Bruce, Leishman and others was performed, the present generation of medical officers of the army serving in India must need look with gratitude to the way in which modern science is encouraged and laboratories are equipped as compared with what existed only ten years ago, when not a single microscope provided by Government was to be found in any military medical institution. Although matters are not yet perfect it may be fairly claimed that since that time the advances made in the Indian sanitary service have marked a new epoch in its history.

EPSOM COLLEGE.

THE annual general meeting of the governors of Epsom College was held on June 26th at the office in Soho-square, London, W. Mr. HENRY MORRIS, the treasurer, occupied the chair, and he was supported by a large number of governors, including Sir R. Douglas Powell, Sir William S. Church, Sir Dyce Duckworth, Sir Constantine Holman, Dr. J. Roberts Thomson, Dr. William Collier, Dr. Frederick Taylor, Dr. F. de Havilland Hall, Mr. J. A. Bloxam, Dr. Frederick Needham, Mr. George Eastes, Mr. J. H. Morgan, Mr. H. W. Kiallmark, Dr. Clement Godson, Dr. H. Hetley, Dr. St. Clair B. Shadwell, Mr. G. H. Makins, Dr. Guthrie Rankin, Mr. John Adams, Mr. Bilton Pollard, Dr. Charles Drage, Mr. W. F. Haslam, and Mr. A. Pearce Gould.

The SECRETARY having read the notice convening the meeting, read the list of successful candidates as under:—

	Votes.
PENSIONERSHIP.	
1. Price, Charles R.	4179
FOUNDATION SCHOLARSHIPS.	
1. Forbes, George F. M.	7593
2. Stearn, Ernest R.	7521
3. Sheperd, Albert V. W.	6438
4. Hoskyns-Abrahall, T....	6405
5. Elphick, Harry N. K....	6269
6. Hains, Ronald C.	5857
7. Colman, Charles W. T.	5528
R. R. CHEYNE ANNUITY.	
1. Dix, Fanny	6224

The Secretary reported that at the council meeting, which would take place immediately after the annual general meeting, Mr. Herbert F. H. Barham would be appointed a Pugh pensioner under By-law 20, a vacancy having arisen.

In moving the adoption of the report of the council to the governors, the CHAIRMAN referred to the great loss which the council had suffered by the death of two members of their body, Dr. John Henry Galton, a vice-president of the College, and Mr. Reginald Harrison. He said that it was difficult to express adequately the loss which the College had sustained by the death of Dr. Galton who rendered valuable services as chairman of the works committee throughout a very trying period whilst the extensive drainage and sanitary operations at the College were being carried out. Mr. Reginald Harrison was so dear a friend of many present that his loss was felt to be of a personal character.

The report stated that the council was glad to be able to present a satisfactory financial statement for the year 1907. Although it was necessary to spend a sum of £1464 15*s*. 7*d*. on special works at the College and on the completion of the drainage operations, the surplus shown on the income and expenditure account for the year amounted to £1968 19*s*. 6*d*. The council wished to draw the attention of the governors to the existing arrangements in connexion with the election of pensioners and foundation scholars as follows: (*a*) Governors who do not wish to be applied to for votes may have an asterisk placed against their names in the printed list of subscribers to show that they are not to be canvassed; (*b*) the public polling day has been abolished for many years, hence applicants and their friends are not required to go to the expense of attending the annual general meeting of the governors at which pensioners and foundation scholars are elected; (*c*) no exchange of votes is permitted at the office and no assistance or advice in this respect is ever given by the officials; (*d*) the relative claims of all candidates for pensionerships and foundation scholarships are carefully considered annually by the selection committee, and the council issue with each voting paper a list of the candidates whose cases, in the opinion of that committee, are the most urgent; and (*e*) although candidates are at liberty to apply for votes to those governors who are willing to be canvassed, the council do not recognise the system of canvassing and no assistance in the drafting of canvassing cards is given by the officials.

The council had given careful consideration to a scheme for the erection of a new building to provide further class rooms, better accommodation for teaching science, and a day boys' common room. Owing to the funds in hand being insufficient for this purpose they at one time feared that the work would have to be postponed, but owing to the kindness of Mrs. Markham Skerritt, who had advanced a sum of £5000 to the College on favourable terms, the new building would be erected forthwith and the laboratories, to be called for ever the "Markham Skerritt Laboratories," would be of such a character and so well equipped as to afford efficient means for practical instruction in physics and biology to all the boys. On Founder's Day last year a memorial east window in the College chapel, which had been erected at a cost of £700 by contributions from old Epsomians and other friends of the school in commemoration of the jubilee of the opening of the College, was dedicated by the Dean of Winchester. Since the last annual general meeting the basement and ground floor corridors in the main College building, with the rooms opening on to them, and the first and second floor corridors had been heated by the "Reck" circulator system and a hot-water supply had been provided throughout the College, at a cost of £679 for the two systems. A block of buildings containing a new box-room, a new lavatory, and an extension of the latrines had also been provided.

Since the last report P. W. Green had gained an open scholarship at St. Mary's Hospital and R. F. Eminson had gained one at Charing Cross Hospital, whilst B. S. C. Hutchinson had passed into Sandhurst (thirty-fifth place). 12 boys had passed the whole or a part of the Preliminary Scientific Examination for the degree of M.B., B.S. of the University of London; 12 boys had passed the matriculation examination of the same University; 11 boys had gained the higher certificate of the Oxford and Cambridge Schools Examination Board, and 27 had gained the lower certificate. The numbers of boys in the school were as follows: 50 foundation scholars, 7 council exhibitioners, 158 other boarders in the College, 35 boarders in masters' houses, and 22 day boys; total 272.

The motion for the adoption of the report having been seconded by Sir CONSTANTINE HOLMAN, it was carried unanimously.

After the formal business of electing members of the council and the auditors, Sir WILLIAM CHURCH, the chairman of the council, proposed a vote of thanks to Mr. Henry Morris for the great services which he rendered to the institution as treasurer, and for his able conduct in the chair. This was seconded by the Rev. E. W. NORTHEY and carried by acclamation.

MEDICINE AND THE LAW.

The Lunacy Act: A Prosecution.

AT Brighton Borough Bench, on June 25th, Mr. William Henry Compton was summoned by the Commissioners in Lunacy under the provisions of the Lunacy Act, 1890, for having charge on April 7th of a person who was a lunatic without complying with the Act relating to certification and reception. There were three summonses in all. The patient had been a schoolmaster in Buckinghamshire but became very ill through overwork. He was perfectly rational except on one point which was that he fancied that when teaching he suddenly had had a gift of singing conferred upon him, that he could sing anything at sight, and in consequence, that he was the most important person in the world. By the advice of his medical attendant his son removed him to Brighton, where, after a few days, he took up his residence at the house of the defendant, the terms to be £4 4s. per week. The defendant, according to the evidence in the police-court, treated the case as one of nervous breakdown which might develop into general paralysis. The patient's symptoms were consistent with general paralysis or with nervous breakdown, and he was not, the defendant said, in a state that would have justified him in certifying the patient as of unsound mind. Food was enjoyed, amusements were freely entered into, letters were answered; moreover, he frequently went out alone. On April 16th, however, the patient had a "maniacal outburst" and went to the police. He was taken before the magistrates who ordered his removal to Haywards Heath asylum and he died in the following month. For the defence it was held that during the time when the patient was with the defendant there were no signs particularly indicative of general insanity and nothing to justify the patient being placed under restraint. The magistrates, however, mulcted the defendant in a penalty of £5 and costs, including £2 2s. advocate's fee, on the first summons for taking for payment charge of a lunatic in an unlicensed house. He was ordered to pay the costs on the second summons for receiving for payment a lunatic to board and lodge, and the third summons for detaining two lunatics at his residence, which was not an institution for lunatics or a workhouse, was withdrawn by the Treasury representative. On behalf of the Treasury during the hearing of the case no reflection was cast upon the treatment of the patient or the defendant's professional standing. These cases should prove instructive to medical men who are recommended to lean towards caution when the reception of a patient of doubtful mental condition is proposed to them.

Action for Negligence against a Barber.

A recent appeal against a judgment for £10 10s. and costs recovered in the Kingston county court illustrated the dangers attending the process of being shaved in a public hairdressing establishment or barber's shop and also to some extent made clear the liability of the barber. The plaintiff, a billiard-room manager, according to his own evidence, was shaved in the defendant's shop and there had inflicted upon his throat a cut about an eighth of an inch in length. The barber afterwards wiped his face with a towel and applied some toilet powder with a "puff." Half an hour later the plaintiff noticed irritation from the cut and when he consulted a medical man was informed that he had contracted ringworm. He afterwards suffered sufficiently to incapacitate him for a time from following his occupation. The appeal to the Divisional Court was on the ground that there was no evidence of negligence on the part of the defendant with regard to keeping clean the razors used, and his counsel contended that as the disease might have been contracted in some other way than through the razor with which the cut was made, therefore direct evidence attributing it to the razor was necessary. The court, however, pointed out that there was evidence of a cut rapidly followed by irritation, and was of opinion that this was sufficient for the county court judge to base upon it the conclusion that the disease was communicated when the plaintiff was shaved. Another point raised was that evidence had been wrongly admitted, given by two other customers of the appellant to the effect that they had both at dates previous to that in question contracted the same disease in his shop. Mr. Justice Channell in his judgment held that without the evidence thus objected to there was enough upon which the county court judge might have founded his decision, and also that the disputed evidence was rightly admitted as it tended to prove that the defendant's razors were not kept properly cleansed. It is to be hoped that the report of this case will have been brought to the attention of all those in whose establishments shaving is carried on and particularly where the same brush, the same razor, and the same towel are used upon a large number of customers. In the argument before the Divisional Court a certain amount of discussion took place with regard to the possibility of rendering razors aseptic, and references were made to the precautions taken by surgeons before performing operations and by dentists. That shaving should be carried on everywhere under completely aseptic conditions is a counsel of perfection possible but not likely to be followed. On the other hand, reasonable precautions can, and should, be taken by all hairdressers, and especially by those who shave, which will insure comparative safety for their customers, and such precautions are not fulfilled merely by dipping a razor in warm water before using it upon the customer's face, a proceeding referred to in the argument before the Divisional Court as if it was taken with the object of sterilising the razor and was capable of attaining that end. The danger in barbers' shops does not, however, lie only in the absence of such precautions as science might recommend to those desirous of carrying on their business with absolute safety; it arises from the use of the same water, soap, shaving brushes, towels, powder puffs, and razors for all the chance customers who may drop in without attention to the rules of what may be termed domestic as distinct from scientific cleanliness. There are many establishments in London where customers by no means of the humbler class are satisfied with conditions which in their own homes would fill them with disgust, and complete asepticism is seriously aimed at in very few instances. The skill of the barber is, perhaps, better to be relied on than the cleanliness of his apparatus. On the other hand, the man whose instruments are dirtiest is to some extent the most likely to shave carelessly and to cut his customer.

A Quack's Performances.

Bertram Mortimer, whom some daily newspapers have described as a "medical specialist" and who has practised quackery of a very gross character with unusual audacity, has now in addition to his sentence for stealing luggage in London, and to the term of four years' penal servitude to which he was condemned at Exeter, been ordered to undergo six months' imprisonment for fraud at Swansea. His real name has been mentioned as W. J. Powell, and his *alias* Mortimer has also been spelt Mortimore. Other sentences upon him passed during earlier stages of his career were for procuration and bigamy. In the circumstances, it is to be hoped that when he is released from the various terms of imprisonment now imposed upon him, some of which he will, perhaps, endure concurrently, the police will keep a sharp look-out in order to prevent the renewal of his crimes. Is it also too much to hope that this gentleman's advertisements will be omitted from certain daily newspapers?

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 10th, 1830.

INSANE POOR.

It appears by returns lately made to Parliament, which have just been printed by order of the House of Commons, that the number of pauper lunatics and idiots in the several counties of England and Wales amounts to very nearly ten thousand, 5145 of these being females. By adding to this number, the amount of lunatics ascertained to be confined in public or private asylums, and those in the army and navy, a total of 13,665 is produced,—a mass which, according to the calculations of Sir Andrew Haliday, is three times greater than it was twenty years since. The judicious and humane disposal of such a large and increasing body of paupers, demands and must obtain, through the interference of Parliament, or the benevolence of the wealthy, a more considerate attention than mere parochial care will bestow on them, and this in some counties it has received. In several of them, public lunatic asylums have been established, and have proved highly economical and advantageous, particularly in consequence of the facilities they have afforded for the *early* treatment of the malady. The following statements, extracted from the reports of the Armagh and Wakefield Asylums, furnished a marked confirmation of the benefits resulting from attention to cases of lunacy, while the attack is recent. In the former, within the last year, of 32 old cases admitted, only one recovered. In the Wakefield Asylum, of 44 cases admitted in which the first attack had taken place within the three months, 28 were cured within six months; and, of 23 cases of twelve months standing, nine were restored within two years from admission. We perceive by the pamphlet of Dr. Palmer, a magistrate of Devon and Somerset, that the establishment of a pauper lunatic asylum in the former county also, is under serious consideration, and will probably be carried into effect.

Sale of Spirits of Wine without a License.—The following letter is extracted from the last number of the *Gazette of Health*. It cannot be too widely circulated:—

"Treasury Chambers, May 26, 1830.

"Sir,—Having laid before the Lords Commissioners of his Majesty's Treasury your memorial, praying that you may be permitted to sell spirits of wine, by retail, without license, I am commanded by their Lordships to acquaint you, that your request cannot be complied with. I am, Sir,

Your obedient servant,

"*Geo. R. Dawson.*[*]

"Dr. R. Reece, 8, Bolton Row."

---

[*] Rt. Hon. Geo. Robert Dawson, P.C., of Castle-Dawson, Co. Derry, Ireland, Secretary of the Treasury and later, of the Admiralty.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8722 births and 3662 deaths were registered during the week ending July 4th. The annual rate of mortality in these towns, which had declined in the nine preceding weeks from 15·7 to 11·8 per 1000, was again equal to 11·8 in the week under notice. During the 13 weeks of the past quarter the annual death-rate in these towns averaged only 13·8 per 1000, and in London during the same period it did not exceed 13·3. The lowest annual death-rates in the 76 towns during the week under notice were recorded in Hornsey, Willesden, Walthamstow, and Wallasey, in each of which urban districts the rates were below 5 per 1000; the rates in the other towns ranged upwards, however, to 18·0 in Manchester, 18·2 in Merthyr Tydfil, 18·3 in Bootle, 18·4 in Burnley, and 21·5 in Huddersfield. The death-rate in London during the week did not exceed 10·9. The 3662 deaths in the 76 towns during the week were fewer by two than the number returned in the previous week, and included 299 which were referred to the principal epidemic diseases, an increase of but three upon the low number in the previous week; of these 299 deaths, 92 resulted from diarrhœa, 76 from measles, 63 from whooping-cough, 40 from diphtheria, 22 from scarlet fever, and six from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases last week were equal to a mean annual rate of but 1·0 per 1000, corresponding with the low rate from the same diseases in each of the three preceding weeks; the rate from these diseases in London was again so low as 0·8. No death from any of these epidemic diseases was registered last week in Derby, Norwich, Birkenhead, York, or in 12 other smaller towns; the annual death-rate from these diseases ranged upwards, however, to 2·3 in Rochdale and in Smethwick, 2·7 in Rhondda, 2·8 in Salford, and 3·4 in Merthyr Tydfil. The deaths attributed to diarrhœa in the 76 towns, which had been 63, 64, and 70 in the three preceding weeks, further rose to 92 in the week under notice, and caused annual death-rates equal to 1·1 in Walsall, 1·3 in Coventry, and 2·0 in Merthyr Tydfil. The 76 fatal cases of measles showed, however, a further decline from the numbers returned in the three preceding weeks; the highest annual rates from this disease were 1·2 in Leyton, 1·3 in Salford, 1·8 in Rochdale, and 2·0 in Stockton-on-Tees. The 63 deaths from whooping-cough also showed a further decline of 10 from the decreasing numbers in recent weeks; they caused, however, a rate of 1·4 in Merthyr Tydfil. Of the 40 fatal cases of diphtheria, an increase of five upon the number returned in each of the two previous weeks, ten occurred in London and its suburban districts, and three both in Liverpool and in Birmingham. The 22 deaths from scarlet fever included 11 in London and its suburbs, and three in Liverpool. Only six deaths during the week were referred to "fever" in the 76 towns. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had declined in the nine preceding weeks from 2938 to 2553, had further fallen to 2529 during the week ending July 4th; 322 new cases of this disease were admitted to these hospitals during the week under notice, against 289, 310, and 365 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had steadily declined in the ten preceding weeks from 301 to 107, rose again to 120 in the week under notice, but were seven below the corrected number in the corresponding week of the five years, 1903-07. Six deaths in London were directly referred to influenza during the week. The causes of 29, or 0·8 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 54 other smaller towns; six uncertified causes of death were, however, registered during the week in Liverpool and three in London and in Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 14·7 and 14·5 per 1000 in the two preceding weeks, further declined to 12·5 in the week ending July 4th, a lower rate than had prevailed in these towns in any previous week of this year. During the 13 weeks of the past quarter the annual death-rate in these eight towns averaged 16·4 per 1000, and exceeded by no less than 2·6 the mean rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rates during the week under notice ranged from 10·5 and 10·7 in Aberdeen and Edinburgh to 15·3 in Greenock and 15·6 in Paisley. The 540 deaths in the eight towns showed a decline of 70 from the number returned in the previous week, and included 41 which were referred to the principal epidemic diseases, against 51 and 40 in the two preceding weeks; of these 41 deaths, 13 resulted from whooping-cough, 11 from diarrhœa, seven from "fever," four from scarlet fever, and three from both measles and diphtheria, but not one from small-pox. These 41 deaths were equal to an annual rate of 1·2 per 1000, the mean rate from the same diseases in the 76 English towns during the same week being 1·0. The 13 fatal cases of whooping-cough in the eight towns exceeded by one the number in the previous week, and included six in Glasgow, three in Edinburgh, and two in Aberdeen. The 11 deaths attributed to diarrhœa were fewer by five than the number in the preceding week; six were returned in Glasgow and two in Aberdeen. The seven deaths referred to "fever" exceeded the numbers returned in recent weeks, and included six certified as cerebro-spinal fever; five occurred in Glasgow, and one each in Edinburgh and Leith. The four fatal cases of scarlet fever also showed an increase, including two in Dundee. Diphtheria and measles each caused two deaths in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 73 and 67 in the two preceding weeks, were 68 in the week *under notice*, and were fewer by 12 than the number returned in these towns in the corresponding week of last year. The causes of 15, or 3·4 per cent., of the deaths registered in the eight towns during the week were not stated or not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 16·5 and 16·0 per 1000 in the two preceding weeks, rose again to 17·7 in the week ending July 4th. During the 13 weeks of the past quarter the death-rate in Dublin averaged 20·4 per 1000; the mean rate during the same period did not exceed 13·8 in London and 15·5 in Edinburgh. The 134 deaths of Dublin residents registered during the week under notice showed an increase of 13 upon the number returned in the preceding week, and included 11 which were referred to the principal epidemic diseases, against 14 and 11 in the two preceding weeks. These 11 deaths were equal to an annual rate of 1·5 per 1000, the rate during the week from the same diseases being only 0·8 in London and 0·9 in Edinburgh. Of the 11 deaths from these epidemic diseases in Dublin, seven resulted from measles, two from whooping-cough, and two from scarlet fever, but not one from diphtheria, "fever," diarrhœa, or small-pox. The fatal cases of measles, which had been five and four in the two preceding weeks, rose to seven in the week under notice. The 134 deaths from all causes in the city during the week included 16 of infants under one year of age and 39 of persons aged upwards of 60 years; the deaths of infants showed a marked decline from the numbers returned in recent weeks. Four inquest cases and eight deaths from violence were registered, and 57, or 42·5 per cent., of the deaths during the week occurred in public institutions. The causes of all but one of the 134 deaths registered in Dublin during the week were duly certified; while in Edinburgh the causes of five, or 6·9 per cent., of the 72 deaths were not certified.

THE SERVICES.

The Director-General of the Medical Department of the Royal Navy.

Inspector-General of Hospitals and Fleets James Porter, C.B., Director-General of the Medical Department of the Navy, has been granted the relative rank of Vice-Admiral in His Majesty's Fleet (dated May 11th, 1908).

Royal Navy Medical Service.

Deputy Inspector-General of Hospitals and Fleets Christopher Pearson has been promoted to the rank of Inspector-General of Hospitals and Fleets in His Majesty's Fleet. Fleet Surgeon William Eames has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in His Majesty's Fleet. Deputy Inspector-General of Hospitals and Fleets Howard Todd has been promoted to the rank of Inspector-General of Hospitals and Fleets in His Majesty's Fleet. Fleet Surgeon William Henry Norman has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in His Majesty's Fleet.

The following appointments are notified:—Fleet-Surgeon: E. H. Meaden to the *President*, additional, for London Recruiting Headquarters, temporary. Surgeons: R. H. McGiffin to Royal Marines, Plymouth; and W. Bastian to the *Bulwark*. Civil Practitioner: J. A. Dickie to be Surgeon and Agent at Sandbanks.

Army Medical Service.

Surgeon-General William L. Gubbins, C.B., M.V.O., to be Deputy Director-General, vice Surgeon-General W. J. Fawcett, C.B., M.B. (dated June 24th, 1908).

Royal Army Medical Corps.

Lieutenant Frederick E. Bissell to be Captain (dated June 3rd, 1908).

Lieutenant-Colonel R. S. F. Henderson to be Secretary to the Principal Medical Officer, His Majesty's Forces in India, vice Lieutenant-Colonel H. B. Mathias, D.S.O.

Army Medical Reserve of Officers.

Surgeon-Captain William P. Peake to be Surgeon-Major (dated June 17th, 1908).

Surgeon-Major John A. Jones to be Surgeon-Lieutenant-Colonel (dated Jan. 17th, 1908).

Imperial Yeomanry.

Leicestershire (Prince Albert's Own): Surgeon-Captain Walter W. Nuttall resigns his commission (dated March 31st, 1908).

Volunteer Corps.

Royal Garrison Artillery (*Volunteers*): 1st Berwickshire: Surgeon-Lieutenant Irvine K. Hermon resigns his commission (dated March 31st, 1908). 1st Gloucestershire (Gloucester and Somerset): The undermentioned officer resigns his commission (dated March 31st, 1908): Surgeon-Captain Alexander Ogilvy.

Rifle: 3rd Volunteer Battalion, The Gloucestershire Regiment: The undermentioned officer resigns his commission (dated March 31st, 1908): Surgeon-Captain Frederick St. J. Bullen. 2nd Volunteer Battalion, The Prince of Wales's Volunteers (South Lancashire Regiment): Supernumerary Surgeon-Major Frederic J. Knowles (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, South Lancashire Volunteer Infantry Brigade) to be Surgeon-Lieutenant-Colonel, remaining supernumerary (dated March 24th, 1908).

The Royal Naval Hospital, Devonport.

The Lords of the Admiralty on June 30th officially inspected the Royal Naval Hospital, Devonport. Their lordships were received by the Commander-in-Chief (Admiral Sir W. Fawkes). Amongst others present were Inspector-General H. T. Cox, Deputy-Inspector-General J. J. Dennis, Deputy-Inspector-General F. J. Lilly, and the hospital staff. The officers' block and the medical and surgical wards were inspected. The victualling yard was afterwards visited.

DEATHS IN THE SERVICES.

Deputy Inspector-General of Hospitals and Fleets James Nicholas Joseph O'Malley, R.N. (retired), on June 29th, at his residence, Southsea, in his seventy-seventh year. He entered the service as a surgeon in 1856, was promoted staff-surgeon in 1865, fleet-surgeon in 1877, and retired with the rank of deputy inspector-general of hospitals and fleets ten years later. In 1879 he was fleet-surgeon of the *Boadicea* during the Zulu war (medal).

A GALLANT ACT.

A gallant attempt at rescue from drowning, says the *Army and Navy Gazette* of July 4th, was made on Sunday at Millbank. A boy was playing on the steps by the side of the Westminster borough council's wharf when he fell into the river. The spot is directly opposite to the Royal Army Medical College and Lieutenant J. S. McCombe, R.A.M.C., observing the accident, immediately jumped into the water and did his best to save the lad. The tide was running very strongly, however, and the officer's gallant attempt was unsuccessful. At the inquest Lieutenant McCombe was thanked by the coroner and jury for his brave conduct. He dived several times but was unable to find the boy, whose body was afterwards recovered.

ST. JOHN AMBULANCE BRIGADE.

On July 4th Admiral the Hon. Sir E. R. Fremantle inspected the members of the No. 1 District (Metropolitan Corps) of the St. John Ambulance Brigade, which this year celebrates its twenty-first anniversary, in Hyde Park. The inspecting officer was received by Inspector-General Belgrave Ninnis, R.N., the commissioner of the brigade; Colonel Lees Hall, deputy commissioner of the district; and Mr. J. Cantlie, chief surgeon. After the inspection there was a march past. Admiral Fremantle warmly complimented the company.

THE PHYSICAL TRAINING OF RECRUITS.

The committee appointed under the chairmanship of Surgeon-General Sir Alfred Keogh to investigate and report upon the physiological effects of (1) the food, (2) the training, and (3) the clothing of the army, has presented an interim report dealing with the second heading, and containing valuable recommendations which will be noticed in detail.

Correspondence.

"Audi alteram partem."

THE OLDEST INSTITUTION FOR TREATING SICK CHILDREN.

To the Editor of THE LANCET.

SIR,—I am sorry that I have been guilty of an inaccuracy in my letter of June 19th. My authority for the latter part of my statement was a letter addressed to the governors of this hospital by the founder, Dr. Charles West, who had formerly been attached to the infirmary in the Waterloo-road. In this letter, written in 1877, Dr. West says: "I sought while connected with the infirmary to obtain its conversion into a hospital; a result which has since been attained, though not till several years after the establishment of the hospital in Ormond-street." Sir Samuel Wilks's statement that during the "fifties" children were occasionally taken in as well as women by the institution in the Waterloo-road is quite compatible with Dr. West's statements, though not with mine that "for many years after 1852 the treatment was dispensary treatment only," and I modify it accordingly.

To prevent confusion I should explain that the Hospital for Sick Children does not claim to be the oldest *institution* for treating sick children in this country, but to be the oldest *hospital* for sick children. It was with this object that I wrote my letter in your issue of June 26th. The letter of the secretary of the Waterloo Hospital in the previous number was so worded that any reader without a knowledge of the facts might have inferred that the institution in the Waterloo-road was the oldest children's hospital. My statement that the Great Ormond Street Hospital is the oldest children's hospital in this country rests on good authority—namely, on that of THE LANCET and of the Waterloo Infirmary itself, besides that of many others both lay and medical men.

On May 18th, 1850, THE LANCET published "a statement which has been laid before the public by the committee of the Royal Infirmary for Children in the Waterloo-road," of which the following is an extract:—

> This charity was established in 1816 as an Hospital or Infirmary for Children ...... the great cost of the structure was paid out of money borrowed for the occasion. ...... Shortly afterwards the chief founder of the Charity died and with his death the charity faded and from the bright promise of a Children's Hospital ...... the institution became *comparatively neglected* and existed merely as a Dispensary ...... it is still a Dispensary and not yet a Hospital.

In THE LANCET of March 22nd, 1851, occur the two following passages:—

> The printed report which was circulated through the room showed *that there existed in London only one Dispensary for the special treatment of the Diseases of Children, and neither in this city, nor throughout the British Empire, was there any Hospital exclusively devoted to their reception.*
>
> In THE LANCET nearly 12 months since we took occasion in making some remarks on the Royal Infirmary for Children to express our surprise and regret that no Hospital for Sick Children was to be found in the Metropolis.

In THE LANCET of April 2nd, 1898, in the obituary of Dr. Charles West, you state:—

> "At the same time that he was working at St. Bartholomew's Hospital he was trying, but in vain, to induce the committee of the Dispensary for Women and Children to open a children's hospital, and when he failed he persuaded in January, 1850, eight other gentlemen, one of them *Dr. Bence Jones, to issue an appeal in favour of establishing* such an institution. ...... On March the 19th, 1851, at a public meeting at which *Lord Shaftesbury*, then Lord Ashley, was chairman, the Children's Hospital was founded. A fortnight afterwards what had once been the house of the Court physician, Dr. Meade, 49, Great Ormond-street, was taken for the hospital.

These extracts quoted above are, I think, quite sufficient to establish the claim of the Great Ormond Street Hospital beyond dispute.—I am, Sir, yours faithfully,

STEWART JOHNSON, Secretary.

Hospital for Sick Children, Great Ormond-street, London, W.C.,
July 6th, 1908.

*** In an interesting little controversy the odd position is reached that both parties are right.—ED. L.

THE HENDON EDUCATION COMMITTEE, ITS MEDICAL OFFICER, AND THE GENERAL PRACTITIONER.

To the Editor of THE LANCET.

SIR,—Will you assist me in calling the attention of the profession to an abuse of the Act for the Medical Inspection of School Children which is fraught with grave danger to members of it whose patients, like my own, consist principally of the children of the poor. The intention of the Act is, I believe, simply to prevent children attending school in an unfit condition. It was far from the intention of its promoters to set up a machinery for the revision of the decisions of the general practitioner as to the fitness for school or otherwise of his patients or to pay medical officers to draw children away from the care of their family doctors. But this is what is being done here; needless to say, not by the medical officers themselves but by the local education officials.

I happen to have four patients of school age all suffering from early phthisis. All of these I have, of course, more in the general interest than in their own perhaps, forbidden to attend school, having signed the form provided for that purpose by the local education committee. But with this these officials will not be content. More than once their parents have told me that the attendance officer has invited them to send the boys, whom I have forbidden to attend the school, to the school on such and such a date "to see our own doctor." Now, simultaneously, notices, of which I inclose a copy (see below), have been sent to the parents of all the boys asking them to bring the boys to the council offices to-day to see the "school medical officer." The reason given for this is that "a medical certificate has not recently been provided." The enforcing of these medical certificates, which the local council have not, as has been done in other districts where I practise, paid for when they required them, has been a considerable hardship to our poor people and naturally they consider that, in an illness of so protracted a nature as consumption, one certificate ought to be considered sufficient for a long period of time. As a fact, no request has been made in these cases for a repetition of the certificates, the parents not having been again supplied with the form for the purpose. Had this request been made and not complied with there would have been more excuse for the action of the education officials. What is really happening is that a deliberate attempt is being made, on the plea of carrying out the recent Act, to withdraw from the general practitioner, or at least from one, like myself, who is not in the good books of the officials, the right of saying when a child who is a patient of his may or may not attend school and to make "the school doctor" the sole judge in such cases. If this succeeds the natural result must be that parents will see that they will be saved trouble and also the expense of certificates by employing "the school doctor" to attend their children in place of their family medical man; and even if this were not so but the decision of the family doctor were liable to be revised by "the school doctor" the prestige of the former must suffer in consequence.

In my case the two "school doctors" are personal friends and, of course, in no way to blame for what is being done. But it happens that the local education officials have a grudge against me—and I suspect many of the education committee also—for having had the temerity to publicly attack their administration of the Education Acts in the interests of the children in the Hendon schools, and I have little doubt that this is an attempt of some or other of these persons to injure my practice. But whether so intended or not it is clear that if the Act is to be thus used to oust the general practitioner from his care of the children of his poor patients it will ruin the practices of those whose income largely depends upon such cases. What remedy have I for this? It can easily be carried on without the knowledge of either "the school doctors" or myself. And a time might come when "the school doctor" was no longer a personal friend but possibly a none too scrupulous rival. If other general practitioners are finding themselves in the same predicament, I shall be glad to hear from them with a view of taking combined action if it should prove necessary. And I should value, Sir, your opinion on the proper course to take. I am, Sir, yours faithfully,

HENRY BAZETT, M.A., M.R.C.S. Eng., L.R.C.P. Lond.

Rossall, Hendon, June 26th, 1908.

*** We append the copy of the letter addressed by the secretary of the Hendon education committee to the parent of one of the children who have been absent upon Mr. Bazett's advice, and we fail to see what right he has to summon the parent and child to a consultation with another medical man.

> DEAR SIR,—The Attendance Officer reports that your son Sidney has been away from School for some time owing to illness and that a medical certificate has not recently been provided. This is to inform you that the School Medical Officer will attend the Council Offices at 3.30 P.M. on Friday, when the attendance of your son and yourself is requested.
>
> Yours faithfully,
>
> JAMES ANDERSON,
> Secretary to the Committee.

We trust that Mr. Bazett's suggestion that action is being taken by the Hendon education committee upon private rather than public grounds is an error; but whatever the reason may be which has led the committee to seek to get Mr. Bazett's medical opinion over-ridden by the school medical officer the action is a grave error in policy as well as in manners.—ED. L.

OATMEAL DIET IN THE TREATMENT OF DIABETES.

To the Editor of THE LANCET.

SIR,—In reference to your annotation on the oatmeal diet of diabetes in THE LANCET of June 27th it may be interesting to send you a note of a case recently under my care.

A man, aged 67 years, subject to gouty glycosuria intermittently for a number of years, at length gave evidence of pronounced diabetes. At the same time he took with relish to the morning meal of porridge. Then one day quite suddenly he was reported to me by the nurse to have "gone off" the oatmeal and it was dropped out of his dietary. It was also close about this time that his condition became aggravated—thirst, polyuria, wasting. Within a week the presence of diacetic acid in his urine was found by ferric chloride test. Treatment with the alkalies potass. bicarb. and sod. citrate only slightly delayed the ensuing restlessness, delirium, and coma. I should add that the sugar was for the most part of the time as much as eight grains to the ounce and gangrene had started in the foot at the commencement of my attendance.

I am, Sir, yours faithfully,

Hackney, July 8th, 1908. W. J. V. HARLE.

REGOLADO.

To the Editor of THE LANCET.

SIR,—In the *précis* of the Lombardian lake resorts appearing in THE LANCET last year, Sept. 14th, no mention was made of Regolado, the omission being an oversight on the writer's part. Reposing on the mountain side *vis-à-vis* with Menaggio and slightly to the northward, Regolado is 500 feet above Como lake. The hydropathic establishment which mainly constitutes the resort is attained by a rack-and-pinion railway. I gather during the summer Italians are catered for, though not long since an effort was made to attract winter visitors.—I am, Sir, yours faithfully,

Aldeburgh, Suffolk, June 29th, 1908. H. B. SYMONS.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Labelling of Poisons.

ON June 26th a case came before the Salford stipendiary where a firm of what are called "store chemists" was summoned for a breach of Section 13 of the Pharmacy Act by selling a poison, the bottle containing it not being distinctly labelled with the name and address of the firm. It appears that in May last some laudanum and soap liniment was bought for 2*d*. at one of Messrs. J. L. Smith's shops in Cross-lane and the label only showed that Messrs. J. L. Smith had branches in Manchester, Salford, and Pendleton instead of having the name and the address of the place where it was purchased. For the defence it was urged that the firm was well known and that "it would be a great hardship to have separate labels printed for the bottles at each branch shop." There are various ideas of what constitutes a hardship, but in selling poisons over the counter it is desirable, even for the seller, that mischance or evil intent should be guarded against as far as possible, though it should entail some slight inconvenience, miscalled a "hardship." One of these safeguards is that the purchase of the poison is more easily traced when the label gives the address of the shop where it was bought than where it leaves you free to wander from one "branch" to another through Manchester or Salford. Printing is not in these days very costly, and the "branch" must be very weak if it cannot afford labels of its own. The stipendiary said no doubt the firm was well known, but the Act stated that the name and address where the article was purchased must be given. "It was not a bad case, and there would be a fine of 10*s*. and costs." The sale of poisons should be jealously guarded and no foolish remarks about it being a hardship to carry out the law should be brought forward in favour of relaxing the precautions now existing.

Medical Golfers.

Amid the numerous golf clubs of this part of the world the Manchester and District Medical Golfers' Association holds quite a respectable position. It numbers 200 members and on July 4th 107 competitors met at Worsley for the annual tournament. The day was very hot and the ground was hard, so that the conditions were less than paradisiacal, even to the most enthusiastic devotee of this fascinating and fashionable cult. One of the players found the heat, the hard ground, and the behaviour of the nails in his boots such a trying combination that he took off his boots and played from the third hole in his socks. But the relief thus obtained did not bring him success and his bootless return to the clubhouse was greeted with genial merriment. Dr. H. C. Evison of Salford won the cup and displaced Dr. J. Massey of Pendleton, who, however, took the captain's prize and the Walter gold medal, while Dr. Evison took the silver medal for handicaps of ten. At the tournament Dr. Evison won with a score of 71, and Dr. Massey followed with one of 76. The members are gathered from many parts of Lancashire and Cheshire, some from considerable distances. Even those who have not succumbed to the fascination of the game can understand and appreciate the pleasures and benefits to mind and body which such gatherings afford to men engaged in the daily work of their profession, which, however much it may interest, is often wearying and sometimes depressing.

Lead in a Lancashire Water.

A statement was made at a meeting of the Rochdale town council on July 2nd as to the analysis by the borough analyst of the water supplied to a portion of the district served by the Heywood corporation which showed that it was contaminated with lead. One of the aldermen said that one sample contained 1-5th of a grain and another 0·15 of a grain per gallon, and one of the councillors stated that he had had a son laid aside for eight months from lead poisoning and that a neighbour was suffering in the same way. New houses were being built in that neighbourhood and were being coupled up to the supply of the Heywood corporation. It was claimed that the supply of the Rochdale corporation was "as pure as it could be made." That, however, does not explain the case and merely suggests that the Heywood supply is faulty. Many of the northern towns obtaining their water from moorland districts are in constant peril of lead poisoning and therefore must be constantly guarding against it. It may be that the new lead pipes in the new houses are in part to blame, for the fact that the water may take up lead if it is allowed to stand in them all night is often ignored and the water used without any preliminary emptying of the pipe.

The Sun Fires a Shop.

During the recent hot weather a curious occurrence took place at Nelson. The sun's rays ignited the celluloid articles in a hairdresser's shop and a good deal of damage was done before the fire was got under. Curtains have often been set on fire when bull's-eye lenses have been part of the window decoration, but there do not seem to have been any in this case. It at any rate was a useful reminder of the dangerous inflammability of celluloid.

July 7th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Port Sanitary and Civic Hospitals Administration.

THE port sanitary and hospitals committee of the city council met at the municipal offices on July 3rd and proceeded to inspect the infectious hospitals under the management of the committee. In view of the city council's action at the commencement of the financial year in cutting down by £10,000 the committee's estimates, a special appeal was made by the chairman (Mr. John Utting, M.R.C.S.) that as many members of the city council who could would accompany the committee on its tour of inspection and see the extent of the committee's operations. A large number of members of the council responded to the invitation, including the Lord Mayor (Dr. Richard Caton). The utmost satisfaction was expressed at the thoroughness of the arrangements at the various hospitals. The phthisis ward at Fazakerley attracted special attention. Here 24 beds are available for the treatment of tuberculous patients. Excellent results have already been attained, the salubrious surroundings being much admired. At the conclusion of the day's inspection the company sat down to a repast at Fazakerley Hospital. Mr. Utting, in giving the toast of "The Lord Mayor," said that Dr. Caton was eminently qualified to express an opinion on the administration of the hospitals owing to his life-long association with the medical charities of the city. The Lord Mayor, in reply, said that nearly 40 years ago he was a member of a voluntary committee established to carry on the Netherfield-road Infectious Hospital, supported by voluntary subscriptions. The corporation had not at that time been induced to understand that it was a municipal duty to combat infectious disease and to check its spread. That small committee had a heavy piece of work to provide accommodation for typhus fever, scarlet fever, small-pox, and erysipelas both for the poor and for paying patients, for the hospital in Netherfield-road then was not what it has since become under civic management. The difficulties of carrying on that institution were overwhelmingly great, and, as they could understand, a scarlet fever patient might contract small-pox while in the hospital. He would never forget the joy he felt when the municipality admitted that it was its duty to run the hospital. The city, with a large command of finance, was able to make that hospital structurally satisfactory and to add others. Liverpool to-day was behind no city in Europe in its provision for the treatment of infectious disease. The Fazakerly Hospital was by far the best institution of its kind which he had seen in this country or on the continent, and was as efficient as human wit could make it. One reason why the death-rate of Liverpool was steadily declining was the gradual stamping out of infectious disease, largely through the instrumentality of these admirable hospitals of which the city might well be proud. Mr. Utting, in responding to the toast of his health, said that he had been asked what had become of their old enemy, typhus fever. From the years 1866 to 1875 there were 132 deaths per 100,000 of the population from typhus fever; in the next decade the mortality from that disease fell to 53 per 100,000; ten years later it fell to 6·9 per 100,000; and from 1896 to 1905 the number had been reduced to 3·6; whilst during the last two years it had been reduced to 1·7 per 100,000. That was what had become of their old enemy, typhus fever.

David Lewis Northern Hospital.

The Lord Mayor was present in state at the morning service at St. Luke's Church on July 5th, when an appeal was made in aid of the funds of the David Lewis Northern Hospital. His lordship was accompanied by members of the corporation, the medical staff of the hospital, and members of the committee. There was a large congregation. The service was conducted by the Archdeacon of Liverpool (the vicar of the church) and the sermon was preached by the rector of Sefton. He was authorised to say that the David Lewis Northern Hospital, though prepared to continue its good work, was at the present moment perilously near the end of its resources. A substantial offering was made towards the hospital funds.

University of Liverpool: Faculty of Medicine.

The total number of students in the Faculty of Medicine during the session 1907–08 was 148. The total number of research students attending the different departments was 38. At the examinations for the diploma of tropical medicine held in July, 1907, ten candidates satisfied the examiners; in December, 1907, five passed; and in March, 1908, ten obtained the diploma, making a total of 25 successful candidates. At the examinations for the diploma of public health, four candidates presented themselves in July, 1907, and two passed; in January, 1908, three candidates passed. In July, 1907, the degree of M.D. was conferred on seven graduates, and in March, 1908, on one graduate. Professor Benjamin Moore resigned the office of dean of the faculty in the autumn of 1907, and was succeeded by Mr. Keith W. Monsarrat. The title of Associate Professor of Surgery has been conferred on Mr. William Thelwall Thomas and a lectureship in operative surgery has been created to which Mr. Thomas has also been appointed. Dr. William Carter having resigned the chair of Materia Medica and Therapeutics has been granted the title of Emeritus Professor. On the recommendation of the Medical Faculty Mr. Edmund Owen has been invited to deliver the next William Mitchell Banks memorial lecture. He has accepted the invitation and has chosen Nov. 4th, 1908, as the date.

July 7th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Bideford (Devon) Board of Guardians and the Local Government Board.

AT a meeting of the Bideford board of guardians held last week a letter was received from the Local Government Board in reference to the recent appointment of a non-resident medical officer, the Board stating that there was a well-qualified resident medical man who should have been appointed to the post. The guardians, after some discussion, decided to inform the Local Government Board that although another medical man was staying in the district and had promised to take up his permanent residence in the district, still the guardians did not regard this medical man as a resident within the meaning of the Local Government Board regulations and had consequently not elected him.

District Medical Officers and Agricultural Labourers.

At a meeting of the Tiverton (Devon) board of guardians held on June 29th Mr. Acland Troyte alluded to the idea which prevailed among agricultural labourers that a man with three children had a right to the services of the parish medical officer. He remarked that this was totally erroneous and the quicker it was dispelled the better, and added that several people went to their district medical officer for very trivial things, and he considered that this was the way some people got pauperised. The clerk stated that it was quite irregular for medical men to attend any cases without orders from the relieving officers.

Midwifery Fees and the Barnstaple (Devon) Board of Guardians.

At a meeting of the Barnstaple board of guardians held on July 3rd it was decided to pay the fee of a local medical practitioner who had been called in by a midwife for an urgent case, but the chairman added that when possible a district medical officer must be summoned and the guardians would not be disposed to behave liberally to cases where that was not done.

The Bristol General Hospital.

On June 29th, in the presence of a large gathering, the new wing of the nurses' home in connexion with the Bristol General Hospital was formally opened by Lady Greville Smyth. The new building comprises 32 bedrooms and sitting-rooms, and brings up the accommodation of the home to the requirements of 88 nurses.

Obituary: Benjamin Lamb Powne, M.R.C.S. Eng., L.S.A.

The death occurred suddenly on July 1st of Mr. Benjamin Lamb Powne at his residence, Monmouth House, Chard, Somerset, from angina pectoris. Mr. Powne, who was in his 66th year, had been for many years in practice at Chard where he was much esteemed. He held several appointments, being medical officer to the Post-office, a district medical officer of the Chard union, and also surgeon to various friendly societies and factories. Mr. Powne was extremely popular throughout the district. By his death the poor have lost a kind benefactor and he will be much missed at Chard. Much sympathy is felt with his widow and children.

July 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Lord Rectorship.

Dr. W. Osler, Regius professor of medicine in the University of Oxford, has consented to stand as non-party candidate for the lord rectorship of the University of Edinburgh. The political candidates already adopted are Mr. Churchill, M.P., and Mr. Wyndham, M.P., so that there will be a three-cornered fight. On two previous occasions a non-political candidate has stood for office—Ruskin, who came within 183 votes of victory in 1862, and Carlyle, who in 1871 was elected by a large majority over Lord Beaconsfield. The medical vote is very strong, and should it go completely to Dr. Osler our distinguished *confrère* may head the poll in November.

Glasgow Dental Hospital.

The annual report of the Incorporated Glasgow Dental Hospital contains some interesting statistics and observations regarding the development and tendencies of dental science. The number of patients treated during last year was 9693, an increase of 954 on the previous year. The development of dental science tended in the direction of diminishing extraction operations and in the increase of conservative work. Of the total operations in 1903, 34·5 per cent. were extractions, whereas last year the proportion of extractions was reduced to 28 per cent. Conservative operations upon patients last year showed an increase of 1909 compared with the number for the previous year. At the end of the year there were 45 students on the roll, compared with 35 previously. A laboratory, at a cost of over £100, was fitted up in connexion with the recently established bacteriological department. Notwithstanding the fact that this institution has been established for 23 years and is generally recognised as a charitable institution doing good work, the public subscriptions for the year amounted to £93 16s., which works out at something like 2*d*. per patient treated.

Bequest to the Leanchoil Hospital, Forres.

The late Mr. John Munro of Elgin in his will has directed £1000 to be mortified for Leanchoil Hospital, Forres.

Gifts by Lord Mount-Stephen to the Stephen Cottage Hospital, Dufftown.

At a recent meeting of the directors of the Stephen Cottage Hospital, Dufftown, letters were read from Lord Mount-Stephen intimating that he had decided further to endow the hospital by the purchase of £3000 of debenture bonds, which would greatly increase the revenue of the trust, and that he would also provide £1000 in order that an operating theatre and additional bedroom accommodation might be supplied, so that the hospital would be equipped with all modern requirements. The directors thereupon passed a vote of thanks to Lord Mount-Stephen and the secretary was asked to transmit a copy to his lordship. The meeting thereafter met the architect and went into the plans for the proposed extension.

Deeside District Committee: District Medical Officers.

The Deeside district committee at its last meeting had under consideration several matters of medical interest. The finance subcommittee recommended that the medical officers of the district should be paid fees for the occasions on which they are employed instead of the stated salary annually. The medical officers would get 5s. for every visit. The subcommittee also recommended that antitoxin should be supplied free of charge both for curative and preventive purposes to the poorer classes of the district. Both recommendations were adopted. A letter from the agent of the Convention of Royal Burghs recommending the adoption by the committee of the Notification of Births Act was allowed to lie on the table. Dr. J. P. Watt, medical officer of the county, made a statement with regard to an infectious diseases hospital for the district. The Garroch district had been in communication with a Glasgow firm who offered to keep a moveable hospital in stock at the rate of £14 per annum. When this hospital was required by the committee they would, of course, have to buy it. He suggested that the various distress committees in the county might combine to pay this retaining fee. It was decided to leave the matter over to the meeting in August.

July 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Tuberculosis Prevention (Ireland) Bill.

THE President and Fellows of the Royal College of Physicians of Ireland have issued a memorandum stating their views in connexion with this Bill. They consider, *inter alia*, that it is most desirable that the notification of tuberculosis and all other infectious diseases should be made compulsory throughout Ireland, and that to make the notification of tuberculosis of real value in stopping the spread of the disease the Notification of Infectious Diseases Act, 1889, and the Infectious Diseases Prevention Act, 1890, should be uniformly adopted. They do not consider that the cost of erecting sanatoriums for early cases on any extensive scale would be justified by the results of such treatment but recommend that it should be mandatory on the county councils to provide hospital accommodation for advanced cases, which are a constant danger to the community. The same bodies should be compelled to provide competent bacteriologists as medical superintendents of health, to superintend the work of existing medical officers of health, and to perform diagnostic investigations; their appointments should be "whole time." They further recommend that the Bill should penalise spitting in public, should compel the notification of premises vacated by patients suffering from pulmonary tuberculosis, and should provide for the payment of health visitors and the destruction of cows with tuberculous udders.

The Franco-British Exhibition: the Irish Village.

It is understood that any member of the medical profession visiting the Franco-British Exhibition will be admitted to Ballymaclinton, the Irish village, on simply showing his or her visiting card. All the profits from the village, both from the charges for admission and from the sale of goods, are to be devoted to further the scheme established by Lady Aberdeen for the prevention of consumption in Ireland. In the Irish Village, besides many interesting sights, there is a tuberculosis exhibition, an example of the form of object lesson which has been found so useful in educating the people of Ireland as to the causation, prevention, and treatment of tuberculosis.

Carlow Lunatic Asylum: Question of Appointment of Medical Superintendent.

On June 27th a special meeting of the Joint (Carlow and Kildare) Lunatic Asylum committee was held for the purpose of considering an order from the High Court calling on the committee to proceed to the election of a resident medical superintendent of the asylum possessing the proper qualifications. A letter was read from the Most Reverend Dr. Foley, Bishop of Kildare, in which he strongly recommended a cessation of the attitude of contest which had been adopted, as he considered that it was a reasonable, even a necessary, regulation which required five years' experience of asylum work as a condition precedent to the appointment of a person to the responsible post of resident medical superintendent, and he believed that resistance on this or any other score was sure to be futile. Several members, however, expressed themselves strongly in favour of opposing the conditional order, three of whom intimated their readiness to be held personally liable for any expenses incurred so that the ratepayers should suffer no pecuniary loss, and it was finally resolved (by 11 to 3):—

> At a special meeting of the joint committee of Carlow District Asylum held here on the 26th June to consider a conditional order for mandamus from the High Courts, it was decided to instruct a solicitor to show cause why that order should not be made absolute and to defend the committee in their previous action in reference to the appointment of a resident medical superintendent.

The New Baths at Kingstown.

The new Royal Victoria Baths at Kingstown, which have been erected by the Kingstown urban council at a cost of nearly £11,000, were opened on July 4th, in the presence of a large concourse of visitors, by Mr. A. V. McCormick, chairman of the urban council, who spoke in warm terms of the natural advantages of Kingstown as a beautiful and healthy watering place.

The Royal Hospital for Incurables, Donnybrook.

The annual meeting of the governors and guardians of this hospital was held in the board room on July 2nd. Among those present were: Mr. John Lentaigne (President of the Royal College of Surgeons in Ireland), Sir Arthur V. Macan, Mr. Justice Ross, and a number of the leading representatives of commercial interests. The report which was submitted to the meeting showed that the hospital contains 213 beds which are classified as follows: 32 for cancer, 39 for consumption, and 142 for general diseases. During the past year the average daily number of occupied beds was from 209 to 212, which practically means that the house was always kept full. Eight elections had taken place during the year. 127 applicants had applied for admission, of whom 53 were elected: of these 10 were cases of pulmonary tuberculosis, 12 of cancer, 10 of paralysis and other nervous disorders, six of heart disease, six of rheumatism and allied arthritic affections, and nine of various other diseases. Besides filling the beds at each election—and with a view to meeting casual vacancies which may occur—the governors elect (when suitable cases present themselves) two patients as pensioners, and these receive a regular weekly allowance until a time arrives when they can be conveniently accommodated in the hospital. The average attendance of governors at the eight elections of patients held during the course of the year was 121 and the interest thus evinced in the unhappy sufferers from hopeless disease who are seeking admission is most encouraging to those upon whom the responsibility of the hospital mainly rests. The amount of the ordinary expenditure was £7618, being in excess of that of the previous year by £305. This difference was chiefly due to the increased cost of firing, bedding, and building repairs. On the other side of the account the governors record with satisfaction a gratifying increase in the ordinary income of £221. The subscriptions and donations had also exhibited a welcome increase. Mr. Richard Croker had generously cleared the bank overdraft of £371 in July of last year. The trustees of the late Countess of Pembroke had considerately allocated a sum of £500 to the hospital from the moneys left to them to be expended for charitable purposes in Ireland; the income derived from the invested capital to be applied towards the endowment of a bed in perpetuity. The cost of maintaining a patient within the walls for a whole year was £36 7*s.* 1*d.* In the course of the proceedings the speakers took care to point out that everything was kept abreast of the most advanced science of the day. This was specially conspicuous in relation to the antituberculosis campaign. Mr. Lentaigne, in seconding the motion, which pronounced the hospital worthy of the support of the public, pointed out that one of its special claims was that it was, in a sense, a pioneer institution.

Health of Belfast.

At a meeting of the city council of Belfast held on July 1st it was reported that the average death-rate from all causes between May 17th and June 20th was 16·9, that from zymotic diseases 0·9, and that from chest ailments 5·9 per 1000 of the population. It is satisfactory to note, comparing the present with a similar period during last year, that there is a marked reduction in the number of cases of infectious disease (50 per cent.), and that as compared with the preceding month there is a reduction in the general death-rate of 4·3, 1·3 from chest diseases, and 0·5 from zymotic diseases.

Bees in a Letter-box.

A curious incident occurred a week ago at Limavady, when in their flight a swarm of bees took possession of a wall letter-box in the outskirts of that town in county Derry. The bees remained in this odd resting-place for a considerable time, preventing any letters being posted until an official from the post-office opened the box, when the insects, being fortunately in a quiet humour, were regained by their owner.

Portadown Water-supply.

It is unfortunate that at present the inhabitants of Portadown have a supply of water for eight hours only out of the 24, owing to the fact that the reservoir in the Mourne Mountains for storing water for Portadown and Banbridge is not completed, and the local reservoirs hold when full only a few days' supply, being fed by a stream which runs into the pipe in the mountains, and this stream has been very considerably reduced owing to the present dry hot weather. It is evident that the making of the storage reservoir in the Mourne Mountains has taken longer in its completion than was anticipated.

British University Students in Belfast.

A Congress of Students delegated from various university centres met in Belfast during the last week of June. From a medical point of view the principal feature was the medical committee's report. This committee was appointed to continue the agitation by the Congress for greater uniformity in the standard of examinations at the various universities started by the adoption of the following motion at the British University Students' Congress at Liverpool in July, 1907:—

> That the present lack of uniformity in professional examinations in medicine at the British universities, both with regard to the grouping of subjects and to the standard of knowledge required, is detrimental to the progress of medical education; that it is desirable to establish uniformity both in grouping of subjects at professional examinations in medicine and in the standard of knowledge required for same; and that to meet these requirements a State Examining Board should be appointed to control examinations.

This year's report, with some slight modification, was adopted.

Women's National Health Association.

At a recent meeting of the Ballinrobe branch of this association a motion was adopted calling upon the county council of Mayo to act with the other county councils of Connaught in providing a sanatorium for the province on the lines advocated by the Athlone conference; and another motion was adopted advocating insertion in the Tuberculosis (Ireland) Prevention Bill at present before Parliament of a clause providing for the notification of consumptives landing in Ireland from foreign countries or certain English ports. Copies of the latter resolution were ordered to be sent to the Chief Secretary; to Sir Henry Robinson, Vice-President of the Local Government Board; and to Mr. J. E. Redmond, M.P.

July 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Second Congress of Medical Practitioners.

As I have already written to you, the Second Congress of French Medical Practitioners was held at Lille from June 25th to 28th. The attendance was very satisfactory. After an opening address by Dr. Coppens, the President of the organising committee, and the election of officers, the business began with the reading by Dr. Leredde of the report of the subcommittee upon medical education. It recommends that schools and faculties of medicine should be independent as regards their teaching arrangements and should have free control of their own finances. The State should determine the duration of the curriculum and exercise a supervision over the final examinations, and in this the body of medical practitioners should have a voice through delegates recognised by the State who might, if necessary, be nominated by the professional organisations. M. Sorel declared that the present system of examinations is demoralising to students at the very outset of their studies and that its administration is so bad that it must be done away with. Finally, Dr. Coppens moved that all titles and diplomas should be abolished, and in spite of the intervention of Dr. Hardiviller of Amiens, who tried to defend the *agrégé* system, this motion was adopted by the congress. Another motion which was carried on the same day demanded that hospitals founded for the relief of indigent persons should devote themselves to that class exclusively, except in cases of urgency, when other patients might be treated under conditions. On the next day the topic discussed was the free right of members of benefit societies, victims of industrial accidents, and employees under the departments of public works, to choose their own medical attendants. Several medical men having protested against the system of recruiting (*racolage*) practised by the societies and workmen's organisations which insure against accidents the congress adopted the motion that no body, industrial or otherwise, should be empowered to organise its own medical service for the treatment of workmen's accidents but that the supply of such a service should be left to the medical men themselves and its control vested in the responsible parties.[1] Further, that the original certificate of the accident should be confirmed at the demand of one of the parties interested by a consultation between the practitioner treating the accident and the medical adviser of the employer or of the insurance society concerned. Dr. Pierre Seght of Cannes then read his report upon the compulsory notification of infectious diseases by medical men. He moved that it be obligatory upon every parent, master, or employer of patients suffering from all such complaints to notify the same to the municipal authority by means of a medical certificate written upon a special form by the practitioner in charge of the case. This was adopted, as were certain other motions dealing with the establishment of a tariff of surgical fees and the establishment of a commission composed half of medical men and half of members of departmental boards of works (*conseilleurs généraux*) to act as a court of arbitration in cases of abuse. The Congress finally declared that the holding of public offices by medical men is a constant danger to their professional dignity.

The Treatment of Hypertrichosis.

Dr. Albert Weill made a communication upon this subject to the Society of Medicine of Paris on June 12th. He said that women with hair upon their faces could easily be cured of their disfigurement by radiotherapy if judiciously applied in the manner described by him three years ago, which aims at a depilation without causing any change in the skin. This depilation is temporary, but if it be repeated a certain number of times it becomes permanent. Dr. Weill has treated a considerable number of persons by this method for hair upon the face and the legs, and the æsthetic results in 30 cases which he has been able to follow up have been quite satisfactory.

Buccal Leucoplakia.

M. Landouzy in a paper read before the Academy of Medicine on June 23rd dealt with those white patches which occur in the inner surfaces of the cheeks and the angles of the lips and which are known as smokers' plaques or buccal leucoplakia. He showed that they occur generally in syphilitics and that tobacco-smoking is most often their actual exciting cause. They occur in non-smokers also, but in such cases they are always caused by syphilis, and M. Landouzy, following the opinion which Professor Fournier has stoutly maintained, is so convinced of the fact that these plaques have often given him the cue for the treatment of a case of syphilis which had been missed.

Atoxyl in Sleeping Sickness and Trypanosomiasis.

On June 20th at the Academy of Sciences M. Laveran communicated the results of his researches upon atoxyl, an arsenical preparation of low toxicity, in the treatment of sleeping sickness. The results were encouraging but for the most part incomplete, and as a set-off he has found that the drug may cause dangerous symptoms when it is given in large doses. A research was accordingly indicated to find a chemical derivative which should be as active as, and less toxic than, atoxyl. Ehrlich and Bertheim and Browning have pointed to the acetyl derivative of the drug as combining these properties. M. Salmon has tried it upon certain animals, chiefly monkeys, and obtained good results. The acetyl-atoxyl can be given in doses four times as strong as can the simple drug, and M. Salmon thinks that the new product might well be tried in cases of human trypanosomiasis.

A Murderous Assault upon a Medical Man.

On June 29th, about 3 o'clock in the afternoon, an individual dressed like a respectable working man rang the bell of the detached residence of Dr. Armand Marie who is in charge of the male block of the Villejuif Asylum. He was admitted and asked to see the doctor, who was entertaining Dr. Riche, a practitioner of Bicêtre. Dr. Marie entered his study and bade his visitor be seated. The latter whipped a revolver out of his pocket and placing it against Dr. Marie's chest fired, hitting him at about the level of the right nipple. Dr. Marie fell and his murderous assailant discharged five more shots at him, of which only one struck him, entering the right flank. The report of the shots brought Dr. Riche and some asylum attendants into the room. They arrested the ruffian and took him before the Gentilly magistrate, where he said that his crime had been premeditated. He had been confined in the asylum under Dr. Marie's charge in 1900 and had been discharged six months later. Dr. Marie's condition gives no cause for anxiety and Dr. Riche has succeeded in extracting the two bullets.

Deafness and Hereditary Syphilis.

At a meeting of the Medical Society of Paris on June 12th M. Marcel Nattier described a case which shows how necessary it is to keep in mind the serious manner in which parental syphilis can react upon the children. The case in point was that of a puny child whose father and maternal grandfather had both contracted syphilis before they married. His mother died from general paralysis after giving birth to five children, of whom three died at an early age. When the child was four months old he had severe enteritis which interfered with his development in a marked degree. In his twelfth year his eyes were affected with a manifestation of hereditary syphilis, and in his thirteenth his right ear became completely, and his left ear almost completely, deaf, no treatment being of any avail. The general nutrition, on the other hand, was greatly improved by a methodical course of breathing exercises.

A Home of Rest for the Aged.

In my letter of June 22nd I announced a munificent bequest of 10,000,000 francs to the Public Assistance for the purpose of founding a home of rest for old people which is to be known as the Cousin de Méricourt and Besson Home.

---

[1] For a full discussion of the principles at issue in this dispute our readers are referred to a special article on "The Organisation of the Medical Profession in France," THE LANCET, June 27th, 1908, p. 1875.

on the Chinese authorities. The fight against impure milk-supply in Shanghai is a stubborn one, as the system of fines in force has been found to have little other effect than to increase the price of milk in compensation for losses sustained. At the Shanghai mixed court a Chinese dairyman who had been found guilty of adulterating milk and heavily fined on three previous occasions was again brought before the court charged with a similar offence. The magistrate imposed a fine of 200 dollars, two months' imprisonment, and ten days' cangue—i.e., exposing the delinquent in some public place with his head projecting through a square wooden board on which are written his name and crime. Some years ago (in 1903) a vaccination station was opened at the Shanghai Municipal Laboratory under the direction of Dr. A. Stanley, the health officer. During the first year 520 vaccinations were made, but so impressed have the Chinese become with the efficient protective influence of vaccine lymph that they have come forward in yearly increasing numbers till during last March, in one month alone, no less than 1263 were vaccinated and the most satisfactory feature is that all who submitted themselves had done so quite voluntarily.

June 8th.

Medical News.

UNIVERSITY OF LONDON.—At examinations held in May the following candidates were successful:—

M.B., B.S. EXAMINATION.

Honours.—*†§ William Stephen Fenwick, B.Sc. (bracketed equal with A. Fleming for the University Medal), Charing Cross Hospital; *†‡ Alexander Fleming (bracketed equal with W. S. Fenwick for the University Medal), St. Mary's Hospital; *Arthur Norman Leeming, Guy's Hospital; †§ Edmund Garvin Mack, University College Hospital; †‖ Albert James Walton, B.Sc., London Hospital; § Charles Henry Shorney Webb, Middlesex Hospital; and †§‖ Edward Musgrave Woodman, St. Bartholomew's Hospital.

* Distinguished in Medicine. † Distinguished in Pathology.
‡ Distinguished in Forensic Medicine and Hygiene.
§ Distinguished in Surgery.
‖ Distinguished in Midwifery and Diseases of Women.

Pass.—Wilfrid G. Attenborough, King's College; George Norton Bartlett, Guy's Hospital; Bertram Henry Barton and Harry Blakeway, B.Sc., St. Bartholomew's Hospital; Harry Oliver Blanford, St. Thomas's Hospital; George Archibald Bosson, University College Hospital; Rhoda Hicks Butler and Muriel Constance Bywaters, London (Royal Free Hospital) School of Medicine for Women; Walter Horsfall Chesters, St. Mary's Hospital; Hilda Clark, University of Birmingham; James Aitken Clark, St. Thomas's Hospital; Winifred Julia Cox, London (Royal Free Hospital) School of Medicine for Women; David Morgan Davies, Charing Cross Hospital; Gladys Margaret C. Dunbar, London (Royal Free Hospital) School of Medicine for Women; Guy Stanley Earl, St. George's Hospital; Clara Eglington and Frederick Pearson Fisher, University of Birmingham; William Gilliatt, Middlesex Hospital; Edith Mary Guest, London (Royal Free Hospital) School of Medicine for Women; Charles Edward K. Herapath, University College, Bristol; Frederick George Hitch, London Hospital; Frank G. Hodder-Williams, St. Bartholomew's Hospital; Herbert Stanley Hollis, St. Mary's Hospital; Henry Holroyd, Middlesex Hospital; Eric Crichton Hood, University of Leeds; Hendrik Houwink, London Hospital; Rose Fanny Jordan, London (Royal Free Hospital) School of Medicine for Women; David Judah, University College Hospital; Harold Holmes King, St. Bartholomew's Hospital; Alfred John Lee, University College Hospital; Edward Leslie Martyn Lobb and Oswald Marriott, Guy's Hospital; Edward Kenneth Martin, University College Hospital; John Clarke Mead, St. Bartholomew's Hospital; Florence Muriel Morris, London (Royal Free Hospital) School of Medicine for Women; Ernest Edwin T. Nuthall, St. Thomas's Hospital; Mary O'Brien, London (Royal Free Hospital) School of Medicine for Women; John Parkinson, London Hospital; Evan Williams Parry, St. Thomas's Hospital; James J. Paterson, B.Sc., St. Bartholomew's Hospital; Edward Selby Phipson, University of Birmingham; Robert Bernard Price, St. Bartholomew's Hospital; Rowland Waters Rix, St. Thomas's Hospital; Mona Dew Roberts, London (Royal Free Hospital) School of Medicine for Women; Ernest Littleton Sandiland, London Hospital; Charles Fox Octavius Sankey, St. Thomas's Hospital; Frank Sholl Scott, University College, Bristol; Frederick George Sergeant, University College Hospital; Latimer James Short, University College, Bristol; Thomas Gordon S. Smith, St. Thomas's Hospital; Ethelbert William Squire, St. Mary's Hospital; Hugh Stott, Guy's Hospital; Alfred George Sworn, University College Hospital; Arthur Jessop Symes, St. Bartholomew's Hospital; Arnold Newall Thomas and Robert Evans-Thomas, University College, Bristol; and Margaret Hannah Wild, B.A., London (Royal Free Hospital) School of Medicine for Women.

The following candidates passed in one of the two groups of subjects:—

Group I.—Alicia Pears Aldous, London (Royal Free Hospital) School of Medicine for Women; H. Talbot Sidney Aveline, University College, Bristol; Ralph Brown, Westminster Hospital; Thomas William Higgins Burne, St. Bartholomew's Hospital; Ethel Adelaide Douglas, London (Royal Free Hospital) School of Medicine for Women; Albert Edward Evans, Robert Cecil T. Evans, B.Sc., and Norman Kessen Foster, University College Hospital; Sidney Frank Fouracre, Charing Cross Hospital; Henry Leatham Grabham and William Andrew Morton Jack, St. Thomas's Hospital; William Johnson, Guy's Hospital; Evan John Goronwy Jones, University College Hospital; Elsie Marian Layman, London (Royal Free Hospital) School of Medicine for Women; William Percy Purdom, Guy's Hospital; William Percy Walker, London Hospital; and Sophia Margaret V. Witts, London (Royal Free Hospital) School of Medicine for Women.

Group II.—George Spence Candy and Cecil Colmer, London Hospital; Ernest Neville Cook, University College Hospital; Thomas Evans, Guy's Hospital; Harold Sydney Furness, University College Hospital; Gertrude Gazdar, London (Royal Free Hospital) School of Medicine for Women; Thomas John Hallinan, Charing Cross Hospital; George Blenkhorn Harland, University of Durham; Frederick Whewell Hogarth, Guy's Hospital; Max Herschel E. R. Montesole, St. Thomas's Hospital; Mary Elizabeth Parsons, London (Royal Free Hospital) School of Medicine for Women; William Joseph Petty, St. Thomas's Hospital; Thomas Edwin Pryce, University College Hospital; Rachael Hicks Shelley, London (Royal Free Hospital) School of Medicine for Women; Herbert George Willis and Charles McMoran Wilson, St. Mary's Hospital; and Courtenay Yorke, University of Liverpool.

B.S. EXAMINATION (*for Students who graduated in Medicine in or before May, 1904*).

Pass.—George Hutcheson, London Hospital.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

TRINITY COLLEGE, DUBLIN.—At examinations held recently the following candidates passed in the subjects indicated:—

INTERMEDIATE MEDICAL EXAMINATION.

Part I.—Henry L. W. Woodroffe, Andries A. Louw, James M. Elliott, Robert W. Murphy, Arthur F. B. Shaw, Francis O. Crosslé, William L. English, Thomas L. B. Bookey, Albert E. Malone, Thomas G. Harpur, Thomas W. E. Henry, Edgar N. Bateman, Reginald T. Vaugham, Hugh M'C. Fleming, William O. Halpin, Bernard G. Quinlan, Maurice Moore, Henry P. Harpur, and Robert E. Lee.

Part II.—Andries A. Louw, Charles W. M'Kenny, Charles Pentland, Francis J. A. Keane, William O. Halpin, Ernest W. G. Young, John Gardiner, Hugh R. M. Ferguson, Edward P. Allman-Smith, Gervase Scroope, Richard P. Pollard, and Robert E. Lee.

Purser Medal in Institutes of Medicine.—Henry L. W. Woodroffe.

FINAL MEDICAL EXAMINATION.

Part I.—Thomas A. Hughes, Albert J. Stals, David Duff, Douglas M. Moffatt, Robert E. T. Tatlow, Victor B. Kyle, Eric J. Powell, Cecil P. Smyly, Ralph T. St. J. Brooks, John D. Kernan, Benjamin A. Molyneux, George E. Craig, Adams A. M'Connell, Charles G. S. Baronsfeather, Joseph E. N. Ryan, Henry R. Kenny, and Charles B. Jones.

Part II., Surgery.—Dixie P. Clement, Albert V. J. Richardson, David G. Madill, Johannes C. Pretorius, Ernest C. Lambkin, Samuel F. A. Charles, Charles W. Laird, John A. W. Panton, William E. Hopkins, Robert de C. Wheeler, John A. L. Hahn, Duncan F. Hunter, Richard P. Hadden, James E. M'Causland, Edward J. H. Garstin, William Knapp, and William H. Sutcliffe.

Degree in Dental Science.—Arthur K. Macdonald.

Licence in Dental Science.—James I. Kelly.

PRELIMINARY SCIENTIFIC EXAMINATION.

Physics and Chemistry.—Hubert T. Bates, George H. Culverwell, Eileen M. Hewitt, Charles W. C. Myles, William H. R. M'Carter, Edgar H. Wilkins, Dorothy K. Milne, George Roe, John Colgan, Walter Crane, Jerome H. Counihan, William M. Johnstone, Jane F. Colquhoun, Jacobus M. S. Gericke, John T. Higgins, Thomas J. Magee, Charles T. Judd, Hugh G. Trayer, Charles D. Goodenough, Geoffrey A. Hoffman, William E. Fetherstonhaugh, and Kenneth K. Drury.

Botany and Zoology.—William H. R. M'Carter, James N. Armstrong, William O. W. Ball, Hugh G. Trayer, Cedric C. Mecredy, George Roe, Fred. A. V. Denning, Charles D. Goodenough, John Colgan, Jevan H. Powell, George H. Culverwell, Robert A. Flood, Antonie C. Redelinghuys, Jerome H. Counihan, Henry L. D'O. Duckworth, Walter Crane, Edward S. Johnson, Richard E. Tottenham, Jane F. Colquhoun, John Coulter, Edwin F. O'Connor, William P. Croker, Thomas J. Magee, Kathleen D. Wallace, John A. MacMahon, Kenneth R. Drury, James H. Grove-White, Maurice Horan, Reginald O. Smyth, Arthur P. Draper, James B. Taylor, Oswald V. Burrows, Hawtrey W. Browne, Joseph S. English, James R. Dobson, Thomas V. Oldham, Richard A. Stewart, Robert Hemphill, Geoffrey M. M. Fleming, Edward G. Fishe, Leslie J. Nugent, Eric C. Crichton, Robert H. Lyons, Joseph A. Maxwell, Albert W. D. Magee, and Henry B. F. Dixon.

FOREIGN UNIVERSITY INTELLIGENCE.—*Dorpat* (*Iurieff*): Dr. V. C. Shukoffski has been recognised as *privat-docent* of Children's Diseases.—*Harvard*: Dr. John Warren has been appointed Assistant Professor of Anatomy.—*New York* (*University and Bellevue Hospital Medical College*): Dr. Richard M. Pearce, Professor at Albany Medical College, has been appointed to the chair of Pathology.—*Pisa*: Dr. Andrea Boni has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Rome*: Dr. Edoardo Donetti has been recognised as *privat-docent* of Internal Pathology.—*St. Petersburg* (*Military Medical Academy*): Dr. V. A. Oppel has been promoted to the chair of External Pathology.—*Turin*: Dr. Alberto Aggarrotti has been recognised as *privat-docent* of Experimental Physiology.

UNIVERSITY OF CAMBRIDGE.—The Raymond Horton-Smith prize for 1908 has been awarded to T. R. Elliott, M.A., Trinity College, for his M.D. Thesis on "The Control of the Sphincters in Nervous Lesions." The following deserved honourable mention: J. M. Hamill, M.A., Trinity College; and H. Beckton, M.A., Clare College.

CALEDONIAN MEDICAL SOCIETY.—The twenty-eight annual meeting of the Caledonian Medical Society will be held at the Edinburgh District Asylum, Bangour Village, near Uphall, on Friday, July 24th, under the presidency of Dr. J. Keay of Bangour. The annual dinner of the society has been arranged for the same evening at the Caledonian Station Hotel, Edinburgh.

THE SOCIETY FOR THE PREVENTION AND CURE OF CONSUMPTION IN THE COUNTY OF DURHAM.—The annual meeting of this society was held in the sanatorium at Stanhope on June 27th, and was presided over by Mr. C. E. Thompson in the absence of the president, Lord Barnard. The adoption of the annual report was moved by Dr. W. Robinson of Sunderland and seconded by Councillor Elliott of Gateshead. The report referred to the preventive work of the year and drew attention to the rapid fall in the death-rate from consumption in the county since 1900, from nearly 14 per 10,000 persons living to nearly 11 per 10,000 in 1906, and attributed this remarkable fall to the wider appreciation of the principles advocated by the society during the last ten years. It appealed for £6000 to provide a second sanatorium to be used for women only, which is about to be provided, as the 45 beds at Stanhope are quite insufficient. 154 patients had been admitted during the year, but only one-third of these were in the curable stage of the disease. Local and other authorities sent 72 patients, and workmen subscribing 1*s.* a year 56 patients. The following is taken from Dr. J. Gray's excellent report. A new classification of patients (Dr. Turban's), as recommended by Dr. H. T. Bulstrode of the Local Government Board, had been adopted. 140 patients who had been under treatment four weeks and upwards had been discharged during the year with the following results: Of 51 patients who had the disease slightly and affecting one lobe or two half-lobes of the lungs (*Degree 1*) 23, or 45·1 per cent., left apparently cured and 43 returned to work. The average gain in weight was 21·1 pounds and the average stay was 15·6 weeks. Of 31 patients with consumption slight but more extensive than in Degree 1 affecting at most two lobes, or with severe disease and affecting one lobe only (*Degree 2*), there were no cures, but 22 were very much improved and 17 went back to work. The average gain in weight was 16·5 pounds and the average stay was 16·2 weeks. Of 58 patients with severe or very advanced disease (*Degree 3*) none were cured, 28 were very much improved, and 24 were restored to work, their average stay being 14·4 weeks and gain in weight 13·9 pounds. These figures show early treatment to be absolutely necessary for success and the after-results tell the same tale, as shown by the inquiry on April 30th last into the condition of 792 patients who had been treated in the sanatorium in the previous eight years. The after-results were as follows:—*Degree 1.* Of 267 patients in this class 239 were restored to work and 136 are still at work and have been so for periods varying from some months to seven and three-quarter years. 50 have been lost sight of, and as these were among the best cases on discharge most are probably still at work. It is interesting to note that of 14 discharged more than seven years ago half are still at work and only two are dead. *Degree 2.* Of 208 patients in this class 134 were restored to work, 42 are still at work, and 30 have been lost sight of. *Degree 3.* Of 317 patients in this class 130 were restored to work, only 44 of whom are still at work, and 16 are lost sight of. Whilst the after-results in the first class are excellent, those of the other two classes need cause no disappointment considering the shortness of their stay in the sanatorium (under four months) and the poverty and bad surroundings of many of the patients; and even to them and their friends the educational value of a stay in the sanatorium is great, and a proportion of the patients have been restored to work for months or years. An after-care association and a working outdoor colony would improve these results greatly. The ordinary income was £3155, including £255 in 1*s.* yearly subscriptions from workmen, £1139 from local authorities which subsidise beds (at 30*s.* per week), and £827 from patients who pay weekly sums varying up to £2 2*s.* per week according to their circumstances. The ordinary expenditure was £2112. The average number of patients per day was 41·1, the cost of each patient per week was 18*s.* 6¼*d.*, and the average stay in the sanatorium was 13·8 weeks. The election of officers for the year and votes of thanks concluded the meeting.

LUNACY IN SOMERSET.—At a meeting of the Somerset county council held on June 29th it was reported that there were 1560 patients in the county asylum, compared with 1495 for the corresponding period of 1907.

CHILDREN'S EYESIGHT IN MONMOUTHSHIRE.—The elementary subcommittee of the Monmouthshire education committee at its meeting on June 30th reported that 600 cases of defective eyesight among the school children of the county had been satisfactorily dealt with.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Eugen Albrecht, director of the Institute of Pathological Anatomy, Frankfort, suddenly, at the age of 36 years. He was editor of the *Frankfort Pathological Journal*.—Dr. Auguste Reverdin, professor of surgery in Geneva.—Dr. J. Boy-Teissier of the Marseilles hospitals.—Dr. Stephan, head of the scientific department of the Antarctic expedition of the German navy.

PRESENTATION TO A MEDICAL PRACTITIONER.—On July 2nd Mr. Richard Macartney, L.R.C.P., L.R.C.S. Edin., was the guest of the evening at a public dinner held at Cinderford (Gloucestershire) under the presidency of Mr. M. Colchester Wemyss, chairman of the Gloucestershire county council. After the dinner the chairman, on behalf of the subscribers, presented Mrs. Macartney with a canteen of silver and Mr. Macartney received a cheque for £180. The presentations were made on the occasion of the silver wedding of Mr. and Mrs. Macartney to give expression to the respect felt for them in the district.

THE SOCIALIST MEDICAL LEAGUE.—At the first meeting of this league held on June 25th it was agreed that membership should be limited to registered British medical practitioners and dentists and that medical and dental students and non-British practitioners should be admitted as associates. The annual subscription was fixed at 5*s.* for qualified practitioners and 1*s.* for students. It was arranged to hold a yearly meeting during the annual meeting of the British Medical Association and in the same town. Dr. A. Salter (London) was elected chairman, Dr. Williams (Eastbourne) treasurer, and Mr. M. D. Eder (London) secretary to serve during the first year, together with a committee of 10 members.

THE WESTERN VALLEYS MEDICAL ASSOCIATION.—A meeting of the medical practitioners of the Western Valleys (Mon.) was held at Crumlin on June 18th to consider the advisability of forming an association on similar lines to that already in existence in the Eastern Valleys. There was a large and representative attendance, and it was unanimously decided to form an association to be called "The Western Valleys Medical Association," the principal objects being to promote good feeling and *esprit de corps* amongst the members; to discuss and mutually settle all medical matters in the district; to safeguard the interests of the profession generally; to discuss medico-ethical and kindred subjects affecting the profession, and to read papers and show interesting cases.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The honorary general secretary of this association draws our attention to the fact that in our announcement of the third International Congress on the Care and Treatment of the Insane, to be held in Vienna in October (THE LANCET, May 23rd, p. 1502), we named inadvertently three gentlemen as members of the British committee. They are, in fact, members of the Scottish committee. He adds that his association, at the request of the executive committee of the congress, appointed a committee at its recent meeting in London consisting of the following gentlemen:—Dr. Maurice Craig, Dr. Robert Jones, Dr. Charles A. Mercier, Dr. R. Percy Smith, Dr. T. Outterson Wood, and Dr. C. Hubert Bond, with power to add to their on the Chinese authorities. The fight against impure milk-supply in Shanghai is a stubborn one, as the system of fines in force has been found to have little other effect than to increase the price of milk in compensation for losses sustained. At the Shanghai mixed court a Chinese dairyman who had been found guilty of adulterating milk and heavily fined on three previous occasions was again brought before the court charged with a similar offence. The magistrate imposed a fine of 200 dollars, two months' imprisonment, and ten days' cangue—i.e., exposing the delinquent in some public place with his head projecting through a square wooden board on which are written his name and crime. Some years ago (in 1903) a vaccination station was opened at the Shanghai Municipal Laboratory under the direction of Dr. A. Stanley, the health officer. During the first year 520 vaccinations were made, but so impressed have the Chinese become with the efficient protective influence of vaccine lymph that they have come forward in yearly increasing numbers till during last March, in one month alone, no less than 1263 were vaccinated and the most satisfactory feature is that all who submitted themselves had done so quite voluntarily.

June 8th.

Medical News.

UNIVERSITY OF LONDON.—At examinations held in May the following candidates were successful:—

M.B., B.S. EXAMINATION.

Honours.—*†§ William Stephen Fenwick, B.Sc. (bracketed equal with A. Fleming for the University Medal), Charing Cross Hospital; *†‡ Alexander Fleming (bracketed equal with W. S. Fenwick for the University Medal), St. Mary's Hospital; * Arthur Norman Leeming, Guy's Hospital; †§ Edmund Garvin Mack, University College Hospital; †‖ Albert James Walton, B.Sc., London Hospital; § Charles Henry Shorney Webb, Middlesex Hospital; and †§‖ Edward Musgrave Woodman, St. Bartholomew's Hospital.

* Distinguished in Medicine. † Distinguished in Pathology.
‡ Distinguished in Forensic Medicine and Hygiene.
§ Distinguished in Surgery.
‖ Distinguished in Midwifery and Diseases of Women.

Pass.—Wilfrid G. Attenborough, King's College; George Norton Bartlett, Guy's Hospital; Bertram Henry Barton and Harry Blakeway, B.Sc., St. Bartholomew's Hospital; Harry Oliver Blanford, St. Thomas's Hospital; George Archibald Bosson, University College Hospital; Rhoda Hicks Butler and Muriel Constance Bywaters, London (Royal Free Hospital) School of Medicine for Women; Walter Horsfall Chesters, St. Mary's Hospital; Hilda Clark, University of Birmingham; James Aitken Clark, St. Thomas's Hospital; Winifred Julia Cox, London (Royal Free Hospital) School of Medicine for Women; David Morgan Davies, Charing Cross Hospital; Gladys Margaret C. Dunbar, London (Royal Free Hospital) School of Medicine for Women; Guy Stanley Earl, St. George's Hospital; Clara Eglington and Frederick Pearson Fisher, University of Birmingham; William Gilliatt, Middlesex Hospital; Edith Mary Guest, London (Royal Free Hospital) School of Medicine for Women; Charles Edward K. Herapath, University College, Bristol; Frederick George Hitch, London Hospital; Frank G. Hodder-Williams, St. Bartholomew's Hospital; Herbert Stanley Hollis, St. Mary's Hospital; Henry Holroyd, Middlesex Hospital; Eric Crichton Hood, University of Leeds; Hendrik Houwink, London Hospital; Rose Fanny Jordan, London (Royal Free Hospital) School of Medicine for Women; David Judah, University College Hospital; Harold Holmes King, St. Bartholomew's Hospital; Alfred John Lee, University College Hospital; Edward Leslie Martyn Lobb and Oswald Marriott, Guy's Hospital; Edward Kenneth Martin, University College Hospital; John Clarke Mead, St. Bartholomew's Hospital; Florence Muriel Morris, London (Royal Free Hospital) School of Medicine for Women; Ernest Edwin T. Nuthall, St. Thomas's Hospital; Mary O'Brien, London (Royal Free Hospital) School of Medicine for Women; John Parkinson, London Hospital; Evan Williams Parry, St. Thomas's Hospital; James J. Paterson, B.Sc., St. Bartholomew's Hospital; Edward Selby Phipson, University of Birmingham; Robert Bernard Price, St. Bartholomew's Hospital; Rowland Waters Rix, St. Thomas's Hospital; Mona Dew Roberts, London (Royal Free Hospital) School of Medicine for Women; Ernest Littleton Sandiland, London Hospital; Charles Fox Octavius Sankey, St. Thomas's Hospital; Frank Sholl Scott, University College, Bristol; Frederick George Sergeant, University College Hospital; Latimer James Short, University College, Bristol; Thomas Gordon S. Smith, St. Thomas's Hospital; Ethelbert William Squire, St. Mary's Hospital; Hugh Stott, Guy's Hospital; Alfred George Sworn, University College Hospital; Arthur Jessop Symes, St. Bartholomew's Hospital; Arnold Newall Thomas and Robert Evans Thomas, University College, Bristol; and Margaret Hannah Wild, B.A., London (Royal Free Hospital) School of Medicine for Women.

The following candidates passed in one of the two groups of subjects:—

Group I.—Alicia Pears Aldous, London (Royal Free Hospital) School of Medicine for Women; H. Talbot Sidney Aveline, University College, Bristol; Ralph Brown, Westminster Hospital; Thomas William Higgins Burne, St. Bartholomew's Hospital; Ethel Adelaide Douglas, London (Royal Free Hospital) School of Medicine for Women; Albert Edward Evans, Robert Cecil T. Evans, B.Sc., and Norman Kessen Foster, University College Hospital; Sidney Frank Fouracre, Charing Cross Hospital; Henry Leatham Grabham and William Andrew Morton Jack, St. Thomas's Hospital; William Johnson, Guy's Hospital; Evan John Goronwy Jones, University College Hospital; Elsie Marian Layman, London (Royal Free Hospital) School of Medicine for Women; William Percy Purdom, Guy's Hospital; William Percy Walker, London Hospital; and Sophia Margaret V. Witts, London (Royal Free Hospital) School of Medicine for Women.

Group II.—George Spence Candy and Cecil Colmer, London Hospital; Ernest Neville Cook, University College Hospital; Thomas Evans, Guy's Hospital; Harold Sydney Furness, University College Hospital; Gertrude Gazdar, London (Royal Free Hospital) School of Medicine for Women; Thomas John Hallinan, Charing Cross Hospital; George Blenkhorn Harland, University of Durham; Frederick Whewell Hogarth, Guy's Hospital; Max Herschel E. R. Montesole, St. Thomas's Hospital; Mary Elizabeth Parsons, London (Royal Free Hospital) School of Medicine for Women; William Joseph Petty, St. Thomas's Hospital; Thomas Edwin Pryce, University College Hospital; Rachael Hicks Shelley, London (Royal Free Hospital) School of Medicine for Women; Herbert George Willis and Charles McMoran Wilson, St. Mary's Hospital; and Courtenay Yorke, University of Liverpool.

B.S. EXAMINATION (*for Students who graduated in Medicine in or before May, 1904*).

Pass.—George Hutcheson, London Hospital.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

TRINITY COLLEGE, DUBLIN.—At examinations held recently the following candidates passed in the subjects indicated:—

INTERMEDIATE MEDICAL EXAMINATION.

Part I.—Henry L. W. Woodroffe, Andries A. Louw, James M. Elliott, Robert W. Murphy, Arthur F. B. Shaw, Francis O. Crosslé, William L. English, Thomas L. B. Bookey, Albert E. Malone, Thomas G. Harpur, Thomas W. E. Henry, Edgar N. Bateman, Reginald T. Vaugham, Hugh M'C. Fleming, William O. Halpin, Bernard G. Quinlan, Maurice Moore, Henry P. Harpur, and Robert E. Lee.

Part II.—Andries A. Louw, Charles W. M'Kenny, Charles Pentland, Francis J. A. Keane, William O. Halpin, Ernest W. G. Young, John Gardiner, Hugh R. M. Ferguson, Edward P. Allman-Smith, Gervase Scroope, Richard P. Pollard, and Robert E. Lee.

Purser Medal in Institutes of Medicine.—Henry L. W. Woodroffe.

FINAL MEDICAL EXAMINATION.

Part I.—Thomas A. Hughes, Albert J. Stals, David Duff, Douglas M. Moffatt, Robert E. T. Tatlow, Victor B. Kyle, Eric J. Powell, Cecil P. Smyly, Ralph T. St. J. Brooks, John D. Kernan, Benjamin A. Molyneux, George E. Craig, Adams A. M'Connell, Charles G. S. Baronsfeather, Joseph E. N. Ryan, Henry R. Kenny, and Charles B. Jones.

Part II., Surgery.—Dixie P. Clement, Albert V. J. Richardson, David G. Madill, Johannes C. Pretorius, Ernest C. Lambkin, Samuel F. A. Charles, Charles W. Laird, John A. W. Panton, William E. Hopkins, Robert de C. Wheeler, John A. L. Hahn, Duncan F. Hunter, Richard P. Hadden, James E. M'Causland, Edward J. H. Garstin, William Knapp, and William H. Sutcliffe.

Degree in Dental Science.—Arthur K. Macdonald.

Licence in Dental Science.—James I. Kelly.

PRELIMINARY SCIENTIFIC EXAMINATION.

Physics and Chemistry.—Hubert T. Bates, George H. Culverwell, Eileen M. Hewitt, Charles W. C. Myles, William H. R. M'Carter, Edgar H. Wilkins, Dorothy K. Milne, George Roe, John Colgan, Walter Crane, Jerome H. Counihan, William M. Johnstone, Jane F. Colquhoun, Jacobus M. S. Gericke, John T. Higgins, Thomas J. Magee, Charles T. Judd, Hugh G. Trayer, Charles D. Goodenough, Geoffrey A. Hoffman, William E. Fetherstonhaugh, and Kenneth K. Drury.

Botany and Zoology.—William H. R. M'Carter, James N. Armstrong, William O. W. Ball, Hugh G. Trayer, Cedric C. Mecredy, George Roe, Fred. A. V. Denning, Charles D. Goodenough, John Colgan, Jevan H. Powell, George H. Culverwell, Robert A. Flood, Antonie C. Redelinghuys, Jerome H. Counihan, Henry L. D'O. Duckworth, Walter Crane, Edward S. Johnson, Richard E. Tottenham, Jane F. Colquhoun, John Coulter, Edwin F. O'Connor, William P. Croker, Thomas J. Magee, Kathleen D. Wallace, John A. MacMahon, Kenneth R. Drury, James H. Grove-White, Maurice Horan, Reginald O. Smyth, Arthur P. Draper, James B. Taylor, Oswald v. Burrows, Hawtrey W. Browne, Joseph S. English, James R. Dobson, Thomas V. Oldham, Richard A. Stewart, Robert Hemphill, Geoffrey M. M. Fleming, Edward G. Fishe, Leslie J. Nugent, Eric C. Crichton, Robert H. Lyons, Joseph A. Maxwell, Albert W. D. Magee, and Henry B. F. Dixon.

FOREIGN UNIVERSITY INTELLIGENCE.—*Dorpat (Jurieff)*: Dr. V. C. Shukoffski has been recognised as *privat-docent* of Children's Diseases.—*Harvard*: Dr. John Warren has been appointed Assistant Professor of Anatomy.—*New York (University and Bellevue Hospital Medical College)*: Dr. Richard M. Pearce, Professor at Albany Medical College, has been appointed to the chair of Pathology.—*Pisa*: Dr. Andrea Boni has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Rome*: Dr. Edoardo Donetti has been recognised as *privat-docent* of Internal Pathology.—*St. Petersburg (Military Medical Academy)*: Dr. V. A. Oppel has been promoted to the chair of External Pathology.—*Turin*: Dr. Alberto Aggarrotti has been recognised as *privat-docent* of Experimental Physiology.

University of Cambridge.—The Raymond Horton-Smith prize for 1908 has been awarded to T. R. Elliott, M.A., Trinity College, for his M.D. Thesis on "The Control of the Sphincters in Nervous Lesions." The following deserved honourable mention: J. M. Hamill, M.A., Trinity College; and H. Beckton, M.A., Clare College.

Caledonian Medical Society.—The twenty-eight annual meeting of the Caledonian Medical Society will be held at the Edinburgh District Asylum, Bangour Village, near Uphall, on Friday, July 24th, under the presidency of Dr. J. Keay of Bangour. The annual dinner of the society has been arranged for the same evening at the Caledonian Station Hotel, Edinburgh.

The Society for the Prevention and Cure of Consumption in the County of Durham.—The annual meeting of this society was held in the sanatorium at Stanhope on June 27th, and was presided over by Mr. C. E. Thompson in the absence of the president, Lord Barnard. The adoption of the annual report was moved by Dr. W. Robinson of Sunderland and seconded by Councillor Elliott of Gateshead. The report referred to the preventive work of the year and drew attention to the rapid fall in the death-rate from consumption in the county since 1900, from nearly 14 per 10,000 persons living to nearly 11 per 10,000 in 1906, and attributed this remarkable fall to the wider appreciation of the principles advocated by the society during the last ten years. It appealed for £6000 to provide a second sanatorium to be used for women only, which is about to be provided, as the 45 beds at Stanhope are quite insufficient. 154 patients had been admitted during the year, but only one-third of these were in the curable stage of the disease. Local and other authorities sent 72 patients, and workmen subscribing 1*s.* a year 56 patients. The following is taken from Dr. J. Gray's excellent report. A new classification of patients (Dr. Turban's), as recommended by Dr. H. T. Bulstrode of the Local Government Board, had been adopted. 140 patients who had been under treatment four weeks and upwards had been discharged during the year with the following results: Of 51 patients who had the disease slightly and affecting one lobe or two half-lobes of the lungs (*Degree 1*) 23, or 45·1 per cent., left apparently cured and 43 returned to work. The average gain in weight was 21·1 pounds and the average stay was 15·6 weeks. Of 31 patients with consumption slight but more extensive than in Degree 1 affecting at most two lobes, or with severe disease and affecting one lobe only (*Degree 2*), there were no cures, but 22 were very much improved and 17 went back to work. The average gain in weight was 16·5 pounds and the average stay was 16·2 weeks. Of 58 patients with severe or very advanced disease (*Degree 3*) none were cured, 28 were very much improved, and 24 were restored to work, their average stay being 14·4 weeks and gain in weight 13·9 pounds. These figures show early treatment to be absolutely necessary for success and the after-results tell the same tale, as shown by the inquiry on April 30th last into the condition of 792 patients who had been treated in the sanatorium in the previous eight years. The after-results were as follows:—*Degree 1.* Of 267 patients in this class 239 were restored to work and 136 are still at work and have been so for periods varying from some months to seven and three-quarter years. 50 have been lost sight of, and as these were among the best cases on discharge most are probably still at work. It is interesting to note that of 14 discharged more than seven years ago half are still at work and only two are dead. *Degree 2.* Of 208 patients in this class 134 were restored to work, 42 are still at work, and 30 have been lost sight of. *Degree 3.* Of 317 patients in this class 130 were restored to work, only 44 of whom are still at work, and 16 are lost sight of. Whilst the after-results in the first class are excellent, those of the other two classes need cause no disappointment considering the shortness of their stay in the sanatorium (under four months) and the poverty and bad surroundings of many of the patients; and even to them and their friends the educational value of a stay in the sanatorium is great, and a proportion of the patients have been restored to work for months or years. An after-cure association and a working outdoor colony would improve these results greatly. The ordinary income was £3155, including £858 in 1*s.* yearly subscriptions from workmen, £1139 from local authorities which subsidise beds (at 30*s.* per week), and £827 from patients who pay weekly sums varying up to £2 2*s.* per week according to their circumstances. The ordinary expenditure was £2112. The average number of patients per day was 41·1, the cost of each patient per week was 18*s.* 6¼*d.*, and the average stay in the sanatorium was 13·8 weeks. The election of officers for the year and votes of thanks concluded the meeting.

Lunacy in Somerset.—At a meeting of the Somerset county council held on June 29th it was reported that there were 1560 patients in the county asylum, compared with 1495 for the corresponding period of 1907.

Children's Eyesight in Monmouthshire.—The elementary subcommittee of the Monmouthshire education committee at its meeting on June 30th reported that 600 cases of defective eyesight among the school children of the county had been satisfactorily dealt with.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Dr. Eugen Albrecht, director of the Institute of Pathological Anatomy, Frankfort, suddenly, at the age of 36 years. He was editor of the *Frankfort Pathological Journal.*—Dr. Auguste Reverdin, professor of surgery in Geneva.—Dr. J. Boy-Teissier of the Marseilles hospitals.—Dr. Stephan, head of the scientific department of the Antarctic expedition of the German navy.

Presentation to a Medical Practitioner.—On July 2nd Mr. Richard Macartney, L.R.C.P., L.R.C.S. Edin., was the guest of the evening at a public dinner held at Cinderford (Gloucestershire) under the presidency of Mr. M. Colchester Wemyss, chairman of the Gloucestershire county council. After the dinner the chairman, on behalf of the subscribers, presented Mrs. Macartney with a canteen of silver and Mr. Macartney received a cheque for £180. The presentations were made on the occasion of the silver wedding of Mr. and Mrs. Macartney to give expression to the respect felt for them in the district.

The Socialist Medical League.—At the first meeting of this league held on June 25th it was agreed that membership should be limited to registered British medical practitioners and dentists and that medical and dental students and non-British practitioners should be admitted as associates. The annual subscription was fixed at 5*s.* for qualified practitioners and 1*s.* for students. It was arranged to hold a yearly meeting during the annual meeting of the British Medical Association and in the same town. Dr. A. Salter (London) was elected chairman, Dr. Williams (Eastbourne) treasurer, and Mr. M. D. Eder (London) secretary to serve during the first year, together with a committee of 10 members.

The Western Valleys Medical Association.—A meeting of the medical practitioners of the Western Valleys (Mon.) was held at Crumlin on June 18th to consider the advisability of forming an association on similar lines to that already in existence in the Eastern Valleys. There was a large and representative attendance, and it was unanimously decided to form an association to be called "The Western Valleys Medical Association," the principal objects being to promote good feeling and *esprit de corps* amongst the members; to discuss and mutually settle all medical matters in the district; to safeguard the interests of the profession generally; to discuss medico-ethical and kindred subjects affecting the profession, and to read papers and show interesting cases.

Medico-Psychological Association of Great Britain and Ireland.—The honorary general secretary of this association draws our attention to the fact that in our announcement of the third International Congress on the Care and Treatment of the Insane, to be held in Vienna in October (THE LANCET, May 23rd, p. 1502), we named inadvertently three gentlemen as members of the British committee. They are, in fact, members of the Scottish committee. He adds that his association, at the request of the executive committee of the congress, appointed a committee at its recent meeting in London consisting of the following gentlemen:—Dr. Maurice Craig, Dr. Robert Jones, Dr. Charles A. Mercier, Dr. R. Percy Smith, Dr. T. Outterson Wood, and Dr. C. Hubert Bond, with power to add to their on the Chinese authorities. The fight against impure milk-supply in Shanghai is a stubborn one, as the system of fines in force has been found to have little other effect than to increase the price of milk in compensation for losses sustained. At the Shanghai mixed court a Chinese dairyman who had been found guilty of adulterating milk and heavily fined on three previous occasions was again brought before the court charged with a similar offence. The magistrate imposed a fine of 200 dollars, two months' imprisonment, and ten days' cangue—i.e., *exposing the delinquent in some* public place with his head projecting through a square wooden board on which are written his name and crime. Some years ago (in 1903) a *vaccination station* was *opened* at the Shanghai Municipal Laboratory under the direction of Dr. A. Stanley, the health officer. During the first year 520 vaccinations were made, but so impressed have the Chinese become with the efficient protective influence of vaccine lymph that they have come forward in yearly increasing numbers till during last March, in one month alone, no less than 1263 were vaccinated and the most satisfactory feature is that all who submitted themselves had *done so quite voluntarily.*

June 8th.

Medical News.

UNIVERSITY OF LONDON.—At examinations held in May the following candidates were successful:—

M.B., B.S. EXAMINATION.

Honours.—*†§ William Stephen Fenwick, B.Sc. (bracketed equal with A. Fleming for the University Medal), Charing Cross Hospital; *†‡ Alexander Fleming (bracketed equal with W. S. Fenwick for the University Medal), St. Mary's Hospital; *Arthur Norman Leeming, Guy's Hospital; †§ Edmund Garvin Mack, University College Hospital; †‖ Albert James Walton, B.Sc., London Hospital; § Charles Henry Shorney Webb, Middlesex Hospital; and †§‖ Edward Musgrave Woodman, St. Bartholomew's Hospital.

* Distinguished in Medicine. † Distinguished in Pathology.
‡ Distinguished in Forensic Medicine and Hygiene.
§ Distinguished in Surgery.
‖ Distinguished in Midwifery and Diseases of Women.

Pass.—Wilfrid G. Attenborough, King's College; George Norton Bartlett, Guy's Hospital; Bertram Henry Barton and Harry Blakeway, B.Sc., St. Bartholomew's Hospital; Harry Oliver Blanford, St. Thomas's Hospital; George Archibald Bosson, University College Hospital; Rhoda Hicks Butler and Muriel Constance Bywaters, London (Royal Free Hospital) School of Medicine for Women; Walter Horsfall Chesters, St. Mary's Hospital; Hilda Clark, University of Birmingham; James Aitken Clark, St. Thomas's Hospital; Winifred Julia Cox, London (Royal Free Hospital) School of Medicine for Women; David Morgan Davies, Charing Cross Hospital; Gladys Margaret C. Dunbar, London (Royal Free Hospital) School of Medicine for Women; Guy Stanley Earl, St. George's Hospital; Clara Eglington and Frederick Pearson Fisher, University of Birmingham; William Gilliatt, Middlesex Hospital; Edith Mary Guest, London (Royal Free Hospital) School of Medicine for Women; Charles Edward K. Herapath, University College, Bristol; Frederick George Hitch, London Hospital; Frank G. Hodder-Williams, St. Bartholomew's Hospital; Herbert Stanley Hollis, St. Mary's Hospital; Henry Holroyd, Middlesex Hospital; Eric Crichton Hood, University of Leeds; Hendrik Houwink, London Hospital; Rose Fanny Jordan, London (Royal Free Hospital) School of Medicine for Women; David Judah, University College Hospital; Harold Holmes King, St. Bartholomew's Hospital; Alfred John Lee, University College Hospital; Edward Leslie Martyn Lobb and Oswald Marriott, Guy's Hospital; Edward Kenneth Martin, University College Hospital; John Clarke Mead, St. Bartholomew's Hospital; Florence Muriel Morris, London (Royal Free Hospital) School of Medicine for Women; Ernest Edwin T. Nuthall, St. Thomas's Hospital; Mary O'Brien, London (Royal Free Hospital) School of Medicine for Women; John Parkinson, London Hospital; Evan Williams Parry, St. Thomas's Hospital; James J. Paterson, B.Sc., St. Bartholomew's Hospital; Edward Selby Phipson, University of Birmingham; Robert Bernard Price, St. Bartholomew's Hospital; Rowland Waters Rix, St. Thomas's Hospital; Mona Dew Roberts, London (Royal Free Hospital) School of Medicine for Women; Ernest Littleton Sandiland, London Hospital; Charles Fox Octavius Sankey, St. Thomas's Hospital; Frank Sholl Scott, University College, Bristol; Frederick George Sergeant, University College Hospital; Latimer James Short, University College, Bristol; Thomas Gordon S. Smith, St. Thomas's Hospital; Ethelbert William Squire, St. Mary's Hospital; Hugh Stott, Guy's Hospital; Alfred George Sworn, University College Hospital; Arthur Jessop Symes, St. Bartholomew's Hospital; Arnold Newall Thomas and Robert Evans Thomas, University College, Bristol; and Margaret Hannah Wild, B.A., London (Royal Free Hospital) School of Medicine for Women.

The following candidates passed in one of the two groups of subjects:—

Group I.—Alicia Pears Aldous, London (Royal Free Hospital) School of Medicine for Women; H. Talbot Sidney Aveline, University College, Bristol; Ralph Brown, Westminster Hospital; Thomas William Higgins Burne, St. Bartholomew's Hospital; Ethel Adelaide Douglas, London (Royal Free Hospital) School of Medicine for Women; Albert Edward Evans, Robert Cecil T. Evans, B.Sc., and Norman Kessen Foster, University College Hospital; Sidney Frank Fouracre, Charing Cross Hospital; Henry Leatham *Grabham and* William Andrew Morton Jack, St. Thomas's Hospital; William Johnson, Guy's Hospital; Evan John Goronwy Jones, University College Hospital; Elsie Marian Layman, London (Royal Free Hospital) School of Medicine for Women; William Percy Purdom, Guy's Hospital; William Percy Walker, London Hospital; and Sophia Margaret V. Witts, London *(Royal Free Hospital) School of* Medicine for Women.

Group II.—George Spence Candy and Cecil Colmer, London Hospital; Ernest Neville Cook, University College Hospital; Thomas Evans, Guy's Hospital; Harold Sydney Furness, University College Hospital; Gertrude Gazdar, London (Royal Free Hospital) School of Medicine for Women; Thomas John Hallinan, Charing Cross Hospital; George Blenkhorn Harland, University of Durham; Frederick Whewell Hogarth, Guy's Hospital; Max Herschel E. R. Montesole, St. Thomas's Hospital; Mary Elizabeth Parsons, London (Royal Free Hospital) School of Medicine for Women; William Joseph Petty, St. Thomas's Hospital; Thomas Edwin Pryce, University College Hospital; Rachael Hicks Shelley, London (Royal Free Hospital) School of Medicine for Women; Herbert George Willis and Charles McMoran Wilson, St. Mary's Hospital; and Courtenay Yorke, University of Liverpool.

B.S. EXAMINATION (*for Students who graduated in Medicine in or before May, 1904*).

Pass.—George Hutcheson, London Hospital.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

TRINITY COLLEGE, DUBLIN.—At examinations *held recently the following candidates passed in the subjects* indicated:—

INTERMEDIATE MEDICAL EXAMINATION.

Part I.—Henry L. W. Woodroffe, Andries A. Louw, James M. Elliott, Robert W. Murphy, Arthur F. B. Shaw, Francis C. Crosslé, William L. English, Thomas L. B. Bookey, Albert E. Malone, Thomas G. Harpur, Thomas W. E. Henry, Edgar N. Bateman, Reginald T. Vaugham, Hugh M'C. Fleming, William O. Halpin, Bernard G. Quinlan, Maurice Moore, Henry P. Harpur, and Robert E. Lee.

Part II.—Andries A. Louw, Charles W. M'Kenny, Charles Pentland, Francis J. A. Keane, William O. Halpin, Ernest W. G. Young, John Gardiner, Hugh R. M. Ferguson, Edward P. Allman-Smith, Gervase Scroope, Richard P. Pollard, and Robert E. Lee.

Purser Medal in Institutes of Medicine.—Henry L. W. Woodroffe.

FINAL MEDICAL EXAMINATION.

Part I.—Thomas A. Hughes, Albert J. Stals, David Duff, Douglas M. Moffatt, Robert E. T. Tatlow, Victor B. Kyle, Eric J. Powell, Cecil P. Smyly, Ralph T. St. J. Brooks, John D. Kernan, Benjamin A. Molyneux, George E. Craig, Adams A. M'Connell, Charles G. S. Baronsfeather, Joseph E. N. Ryan, Henry R. Kenny, and Charles B. Jones.

Part II., Surgery.—Dixie P. Clement, Albert V. J. Richardson, David G. Madill, Johannes C. *Pretorius*, Ernest C. Lambkin, Samuel F. A. Charles, Charles W. Laird, John A. W. Panton, William E. Hopkins, Robert de C. Wheeler, John A. L. Hahn, Duncan F. Hunter, Richard P. Hadden, James E. M'Causland, Edward J. H. Garstin, William Knapp, and William H. Sutcliffe.

Degree in Dental Science.—Arthur K. Macdonald.

Licence in Dental Science.—James I. Kelly.

PRELIMINARY SCIENTIFIC EXAMINATION.

Physics and Chemistry.—Hubert T. Bates, George H. Culverwell, Eileen M. Hewitt, Charles W. C. Myles, William H. R. M'Carter, Edgar H. Wilkins, Dorothy K. Milne, George Roe, John Colgan, Walter Crane, Jerome H. Counihan, William M. Johnstone, Jane F. Colquhoun, Jacobus M. S. Gericke, John T. Higgins, Thomas J. Magee, Charles T. Judd, Hugh G. Trayer, Charles D. Goodenough, Geoffrey A. Hoffman, William E. Fetherstonhaugh, and Kenneth K. Drury.

Botany and Zoology.—William H. R. M'Carter, James N. Armstrong, William O. W. Ball, Hugh G. Trayer, Cedric C. Mecredy, George Roe, Fred. A. V. Denning, Charles D. Goodenough, John Colgan, Jevan H. Powell, George H. Culverwell, Robert A. Flood, Antonie C. Redelinghuys, Jerome H. Counihan, Henry L. D'O. Duckworth, Walter Crane, Edward S. Johnson, Richard E. Tottenham, Jane F. Colquhoun, John Coulter, Edwin F. O'Connor, William P. Croker, Thomas J. Magee, Kathleen D. Wallace, John A. MacMahon, Kenneth R. Drury, James H. Grove-White, Maurice Horan, Reginald O. Smyth, Arthur P. Draper, James B. Taylor, Oswald V. Burrows, Hawtrey W. Browne, Joseph S. English, James R. Dobson, Thomas V. Oldham, Richard A. Stewart, Robert Hemphill, Geoffrey M. M. Fleming, Edward G. Fishe, Leslie J. Nugent, Eric C. Crichton, Robert H. Lyons, Joseph A. Maxwell, Albert W. D. Magee, and Henry B. F. Dixon.

FOREIGN UNIVERSITY INTELLIGENCE.—*Dorpat (Jurieff)*: Dr. V. C. Shukoffski has been recognised as *privat-docent* of Children's Diseases.—*Harvard*: Dr. John Warren has been appointed Assistant Professor of Anatomy.—*New York (University and Bellevue Hospital Medical College)*: Dr. Richard M. Pearce, Professor at Albany Medical College, has been appointed to the chair of Pathology.—*Pisa*: Dr. Andrea Boni has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Rome*: Dr. Edoardo Donetti has been recognised as *privat-docent* of Internal Pathology.—*St. Petersburg (Military Medical Academy)*: Dr. V. A. Oppel has been promoted to the chair of External Pathology.—*Turin*: Dr. Alberto Aggarrotti has been recognised as *privat-docent* of Experimental Physiology.

to compel them to undertake and carry out the duties which Parliament had cast upon them.—Mr. Runciman replied: Yes, sir, my attention has been drawn to certain cases where the local education authority has resolved to take no action under Section 13 of the Act, or has postponed indefinitely the consideration of the question. Steps are being taken both by correspondence and by local investigation to ascertain the manner in which arrangements for medical inspection are being initiated, and a clause has been inserted into the code requiring as a condition of the payment of the annual grant in respect of any school that satisfactory provision should be made for the medical inspection of the children attending the school. Failure on the part of the local authority to comply with the requirements of the Act may therefore in addition to, and not in substitution of, other statutory remedies result in the refusal of, or deduction from, the grant. Special attention has been called to this matter in the prefatory memorandum to the code, and I think the publicity attaching to the code will suffice to apprise the authorities of its requirements. The Board has no control over the salaries payable by local authorities to the officers engaged in medical inspection, except in so far as inadequate remuneration may be found to result in the inefficiency of inspection; and until the various schemes are in working order and the Board has had opportunities of comparing the methods and efficiency of medical inspection in the various areas, I should not be prepared to say whether any particular salaries can be regarded as insufficient.

Mr. Henry Gooch further asked the right honourable gentleman, whether the provision, prescribed in Article 58 (b) of the Code for 1908–09 for the medical inspection of all children admitted to an elementary school on and after August 1st, 1908, and of all children expected to leave school before July 31st, 1909, necessarily included all or any of the requirements specified in the Board of Education's Circular, 576; whether it was necessary that all the above examinations should be conducted by a qualified medical practitioner; and, if the answer be in the negative, which of the above examinations might be conducted by (a) a teacher; (b) a qualified nurse; whether the use of the schedule in the Board of Education's Circular, No. 582, was obligatory, and whether it must be filled up in every particular.—Mr. Runciman answered: As I recently stated to a deputation of which the honourable Member formed a part, inquiries as to the methods or machinery of medical inspection should obviously be addressed to the Board in writing and, if made, will receive prompt attention and, as far as possible, full replies. It is impossible to deal satisfactorily or completely with the matters of detail within the limits of an answer across the floor of the House, and I think I should be exposing both the Board and the local authorities to risk of misunderstanding if I attempted to do so. If the honourable Member communicates with the Board on behalf of a local authority I shall be glad to see that he has a written reply without delay.

Telephones and Disease.

Sir Edward Sassoon asked the Postmaster-General whether he was now in a position to say why the telephone companies should not be called upon to permit the adoption of the flat mouthpiece such as was allowed abroad, instead of the present retrograde and antiquated instrument, in the interests of hygiene and cleanliness.—Mr. Buxton replied: I have no power to call upon the National Telephone Company to adopt any particular form of telephone. The standard patterns now in use are, however, those which are considered most efficient by experts both in this country and in the United States, and it is easy for any subscriber to keep his telephone in a clean and sanitary condition. I am not sure which particular pattern the honourable Member has in view, but if he will give me information with regard to it I will have it examined.

The Dairies, Cowsheds, and Milkshops (Ireland) Order, 1908.

Mr. Hugh Barrie asked the Chief Secretary to the Lord Lieutenant of Ireland whether he had received numerous resolutions from public boards and public meetings recently held in Ireland protesting against the General Order of the Local Government Board respecting dairies, cowsheds, and milkshops; and whether he would defer the enforcement of the Order until the objections to portions of it had been reconsidered and dealt with.—Mr. Birrell (by written answer) replied: A comparatively small number of resolutions taking exception to the Order has been received. The Local Government Board afforded to all local authorities the fullest opportunity of considering the terms of the Order, a draft of it having been circulated in August last with a view to elicit their opinions. Any points made by local authorities were carefully considered, and certain modifications were made in the draft Order before its adoption in February. The Order came into operation on May 1st, and it would be undesirable to take any steps which would impede the local authorities in giving effect to it.

Mr. Hugh Law also asked the right honourable gentleman whether his attention had been drawn to a resolution of the Milford rural district council protesting against the Dairies, Cowsheds, and Milkshops (Ireland) Order, 1908, made by the Local Government Board, and representing that if enforced in their district it would occasion great hardship to the small farmers, who were not in a position to make the required structural alterations or generally to carry out the demands made by the Order; and what action he proposed to take in the matter.—Mr. Birrell furnished the following written reply: The Local Government Board received the resolution in question, and in reply thereto the Board pointed out to the council that it was their duty to arrange for the registration of cowkeepers, dairymen, and purveyors of milk within their district, but seeing that only a small dairying business is carried on there the Board indicated that the work of inspection might be performed by the sanitary sub-officers instead of by specially appointed dairy inspectors. The Board has reason to believe that only a few farmers in this district who habitually sell milk or supply milk to a creamery will be affected by the Order.

Tuesday, July 7th.

The Administration of the Butter Act in Scotland.

Mr. Flynn asked the honourable Member for South Somerset, as representing the President of the Board of Agriculture, whether his attention had been called to the fact that Section 1, Subsection (3), of the Butter and Margarine Act, 1907, was not being carried into effect in Scotland; whether steps were being taken by the Local Government Board to carry out Section 2, Subsection (1) of the same Act; and what action, if any, was being taken by the local authorities in Scotland to put Subsection (2) of Section 1, in regard to powers of inspection, entry, and sampling, into force.—Sir Edward Strachey answered: With regard to the first part of the question the answer is "yes." Steps have been taken and are being taken to give effect to the Act in Scotland. With regard to the second part of the question the Board of Agriculture is carrying out the subsection. As to the third part the Board is inquiring what action is being taken.

Wednesday, July 8th.

Medical Officers in the Highlands.

Mr. Weir asked the Secretary for Scotland whether he would state under what circumstances the appointment of medical officer of health had been conferred in four cases in the Highland crofting counties on officers who did not possess a diploma in sanitary science, as required under Section 54 of the Local Government (Scotland) Act, 1889.—Mr. Sinclair replied: One medical man holds two of the four appointments referred to, so that in three cases the salaries were sanctioned on condition that the medical officer of health should take the diploma in terms of Section 54 of the Local Government (Scotland) Act, 1889. In regard to the fourth appointment, it was given to the county medical officer of the district who was appointed before such a qualification was necessary. It is understood that in none of these cases were the services of a practitioner available who had the special qualifications.

numbers. To these have since been added Dr. B. H. Mumby and Dr. J. Milson Rhodes.

THE TEIGNMOUTH (DEVON) INFIRMARY.—As a result of a fête held at Teignmouth last week the sum of £197 has been raised for the local infirmary.

A WELSH CENTENARIAN.—David Williams, who was born on March 16th, 1804, died on June 15th at Hendre Fawr farm, Pontardulais.

ON July 1st the "new holiday home" which has been given by Dr. C. A. Hingston of Plymouth to the local Young Men's Christian Association was formally opened in the presence of a large gathering.

DONATIONS AND BEQUESTS.—The late Mr. W. H. Trewin has bequeathed £1000 to the funds of the Bideford (Devon) Infirmary and Dispensary.—St. Mary's Hospital has received an anonymous donation of £5000.

CARDIFF INFIRMARY.—Mr. John Cory has promised that if the residents of Cardiff and district will contribute £5000 annually for the next two years to the Cardiff Infirmary he will augment the amount by 25 per cent.

THE SCHOOL DENTISTS' SOCIETY.—A general meeting of the School Dentists' Society took place at the rooms of the Incorporated Society of Medical Officers of Health, 1, Upper Montague-street, Russell-square, London, W.C., on June 22nd. The President, Mr. Sidney Spokes, M.R.C.S., L.D.S. Eng., took the chair, and a paper was read by Mr. Bryan J. J. Wood, L.D.S. Eng., entitled "An Experiment in a School Dental Clinic and its Lessons." A discussion took place and at the close of the proceedings a vote of thanks was accorded to Mr. Wood for his interesting contribution to the Transactions of the society.

A SUMMER HOLIDAY FOR MEDICAL MEN.—The English representative of the Bathing Establishments and Associated Grand Hotels at Roncegno, South Tyrol, is authorised by the proprietor, Dr. Waiz, to invite a small party of British medical men to spend a portion of their holiday at Roncegno. No expense will be attached to the holiday beyond the cost of the railway tickets at party rates to the Austrian frontier, the Imperial Railway Ministration having kindly offered to place special free railway tickets in Austria at the disposal of Dr. Waiz's representative. Further details will be supplied by Mr. Galloway Kyle, 47, Fleet-street, London, E.C.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Children Bill.

THE Children Bill has passed through a Standing Committee of the House of Commons and been ordered to be reported to the House. Its consideration by the Committee extended over two months and 363 amendments and new clauses were moved during that time. The Bill ranges over a wide field of law affecting children, and amongst other matters with which it deals are infant life protection and juvenile smoking. The clauses dealing with the latter subject underwent modification in the course of the discussions and the Government has promised to introduce a provision during the debates on the report stage making it clear that constables and park-keepers shall have no right to search children suspected of having cigarettes in their possession. When the Committee stage was completed on Thursday, July 2nd, an unusually warm compliment was paid to Mr. HERBERT SAMUEL, the Under Secretary to the Home Department, for the ability and tact which he had displayed in taking charge of the Bill. The Chairman of the Committee, Mr. LAURENCE HARDY, declared that in the ten years during which he had presided over standing committees he had never known a Bill conducted in such a business-like manner as this. Mr. SAMUEL attributed the progress made with the Bill primarily to the absence of any controversial spirit in any member of the Committee.

The Royal College of Surgeons in Ireland and the New Dublin University.

In the Standing Committee of the House of Commons which is dealing with the Irish Universities Bill a proposal was made by Mr. CAMPBELL on Monday, July 6th, to include at least one member of the Council of the Royal College of Surgeons in Ireland and another of the Royal College of Physicians of Ireland amongst the Crown nominees to the governing body of the new University having its seat in Dublin. Mr. BIRRELL would not accept this proposal on the ground that it struck at the root of the whole principle on which hitherto he has acted—viz., not to recognise such chartered bodies or any other associations of individuals as being as such entitled to representation. Mr. DILLON remarked that once representation was given to one body all the other professional bodies in Dublin would have a plausible claim to representation. The proposal of Mr. CAMPBELL was ultimately defeated by 18 votes to 8.

The Coroners' Inquests Bill.

The Coroners' Inquests Bill, which proposes to dispense with the compulsory viewing of bodies at coroners' inquests, has passed through its report stage in the House of Commons.

HOUSE OF LORDS.

MONDAY, JULY 6TH.

Nurses' Registration Bill.

Lord AMPTHILL moved the second reading of this Bill, and after some discussion by Lord CREWE and Lord LANSDOWNE the Bill was read a second time, it being understood that their lordships were committing themselves only to the bare principle enunciated and not to the details.

HOUSE OF COMMONS.

THURSDAY, JULY 2ND.

Cases of Lead Poisoning.

Sir CHARLES DILKE asked the Secretary of State for the Home Department whether there had been reported to the Home Office an extraordinary incidence of lead poisoning at the Woodland Pottery, Tunstall; whether a portion of Rule 2 in the amended special rules, established by the award of Lord James of Hereford, declared that if any factory to which the rule applied should, by reason of the occurrence of cases of lead poisoning, appear to the Secretary of State to be in an unsatisfactory condition he might prohibit the use of lead; whether this rule had been put in force; and whether he would consider the propriety of applying it to such cases.—Mr. GLADSTONE replied: Yes, sir. 11 cases of lead poisoning at these works, three of which, however, are doubtful, have been reported to the Factory Department during the current year, as compared with three in 1907, none in 1906, two in 1905, nine in 1904, and one in 1903. Proceedings were taken in April last against the firm and application made under Section 18 for an order prohibiting the works being used until the necessary alterations had been made. On the firm giving an undertaking to remedy the defective arrangements for drying and ware cleaning, to which the heavy incidence of poisoning is attributed, the stipendiary, with the concurrence of the medical inspector and the lady inspector in charge of the case, adjourned the hearing. The alterations, which are a difficult matter and will cost, I understand, some £5000, are now being carried out and are to be completed by August 23rd. As regards the second part of the question, there is such a power as mentioned in the special rules. It is a power which is intended only for very exceptional cases and has not hitherto been used. In view of the action of the stipendiary I do not think I could properly direct action to be taken under this special power at present, but the works will be kept under observation, and if heavy incidence of poisoning continues I shall consider what further action, whether under rule or otherwise, is required.

The Medical Arrangements in Belfast Infirmary.

Mr. DEVLIN asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the report of the Local Government Board inspector, Mr. Agnew, on the Belfast workhouse, and particularly to the inspector's references to the unsatisfactory nature of the nursing and medical arrangements; and whether any explanation had been forthcoming from the guardians with regard to these matters.—Mr. BIRRELL replied: The report in question points out that the number of charge nurses employed in the Belfast Infirmary is too small in proportion to the number of probationers and that in the auxiliary workhouse for consumptives the medical arrangements cannot be considered satisfactory. There are 1600 beds in the infirmary and about 180 nurses, and apart from the matters mentioned the inspector's comments upon the nursing and medical arrangements are most favourable. The guardians have adjourned the consideration of the report in order that it may be printed and circulated amongst them.

Motor Omnibus Accidents in London.

Mr. ALDEN asked the Secretary of State for the Home Department whether he could state the number of accidents, fatal or otherwise, due to motor-omnibuses during the last two months in London and the surrounding districts; in what portion of Greater London had these accidents been most frequent; and what steps he proposed to take to remedy the evil.—Mr. GLADSTONE answered: The number of accidents in the metropolitan police district caused by motor-omnibuses including those which did and did not cause personal injury was 334 in April and 483 in May. Five persons were fatally injured by such accidents in April and 12 in May. The figures for June are not yet available. Such accidents had been most frequent in Oxford-street where 67 occurred, in Barking-road with 30, and in King's-road, Chelsea, with 33 during the time mentioned. As I have often said, the police do their very best under the existing law to put a stop to dangerous driving, but I am considering whether it would not be possible and, if so, whether it would not be desirable, to reduce the speed limit of motor omnibuses to ten miles an hour as a condition of their licence.

MONDAY, JULY 6TH.

The Medical Inspection of School Children.

Mr. TENNANT asked the President of the Board of Education whether his attention had been called to the failure of certain local education committees to carry out their statutory duties of providing for the medical inspection of school children and to the inadequate salaries which some local education authorities proposed to pay for this important duty; whether he proposed to take steps to ascertain the manner in which these duties were about to be performed, and, if so, when these steps would be taken; and whether he proposed to inform the various local education authorities of any measures contemplated

WICH, CITY OF.—Assistant Medical Officer of Health and Bacteriologist. Salary £130 per annum and allowances.

HAM COUNTY BOROUGH.—Assistant Medical Officer of Health. Salary £200 per annum.

ERBOROUGH INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, and washing.

LAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.

EEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician and Two House Surgeons for six months. Salaries at rate of £60 per annum, with board, residence, and laundry.

YAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—House Physician for six months. Salary at rate of £60 per annum, with board, lodging, and washing.

YAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Junior Resident Medical Officer. Salary at rate of £50 per annum, with board and washing.

MARY'S HOSPITAL, London, W.—Honorary Anæsthetist.

MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Demonstrator of Physiology. Salary £150 per annum.

PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road.—Resident Medical Officer. Salary £105 per annum, with residence and attendance.

RBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary £80 per annum, with residence, board, and allowance for laundress.

EFFIELD, EAST-END BRANCH OF THE CHILDREN'S HOSPITAL.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

EFFIELD ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £65 per annum, with board and residence. Also Assistant House Physician. Salary £60 per annum, with board and residence.

REWSBURY, SALOP INFIRMARY.—House Physician. Salary at rate of £60 per annum, with board and apartments.

IGNMOUTH HOSPITAL, S. Devon.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

CTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—Surgeon to In-patients.

ARRINGTON COUNTY BOROUGH.—Assistant Medical Officer of Health. Salary £250 per annum.

ARWICK, HATTON ASYLUM.—Third Assistant Medical Officer. Salary £135 per annum, with board, lodging, attendance, and laundry.

ESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Honorary Physician. Also Junior House Surgeon. Salary at rate of £80 per annum, with board, residence, and washing.

ESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

EST SUSSEX AND CHICHESTER JOINT EDUCATION COMMITTEE.—Medical Inspector of Schools. Salary £350 per annum and expenses.

HITEHAVEN AND WEST CUMBERLAND INFIRMARY.—Resident House Surgeon. Salary £120 per annum, with board and lodging.

OLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £80 per annum, with board, lodging, and laundry.

ORCESTER GENERAL INFIRMARY.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

HE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Accrington, in the county of Lancaster; and at Oughtibridge, in the county of York.

Births, Marriages, and Deaths.

BIRTHS.

ENT.—On July 1st, at Effingham Lawn, Dover, the wife of Charles A. Kent, M.D., of a son.

CATLIFF.—On July 2nd, at 11, Charlotte-street, Brighton, the wife of Harold Scatliff, M.A.; M.R.C.S., of a daughter.

ALTER.—On July 1st, at Wallingford-on-Thames, the wife of Edwin C. Walter, M.R.C.S., L.R.C.P. Lond., of a son.

MARRIAGES.

EITCH—LOCHHEAD.—At The Milton, Colintraive, on July 3rd, by Rev. Dugald M'Cormick, Rothesay, assisted by Rev. Gavin J. Tait, Paisley, and Rev. Alexander M'Gilp, Colintraive, Archibald Leitch, M.B., Ch.B., Cancer Research Laboratories, Royal Infirmary, Dundee, to Ethel Macleod, M.B., Ch.B., daughter of J. M. Lochhead, Sheriff-Clerk of Renfrewshire.

INTO LEITE—WILSON.—On July 6th, at the Church of the Holy Name, Manchester, by the Rev. Bernard Vaughan, S.J., assisted by the Rev. Thomas Brown, S.J., Rector, Hubert Pinto Leite, B.A. Cantab., L.R.C.P. Lond., M.R.C.S. Eng., eldest son of Joaquim Pinto Leite, Vice-Consul for Portugal in Manchester, and Mrs. Pinto Leite, to Dorothy, only child of W. H. Wilson and Mrs. Wilson, late of Manchester. At home, 5, Doughty-street, London, W.C., Sept. 8th, 9th, and 10th.

ATSON REID—FORREST.—On July 1st, at Christ Church, Crookham, Robert Watson Reid, M.B., to Emily Christina Maud, daughter of the late Elton Forrest and Mrs. Forrest.

DEATHS.

HBY.—On July 5th, at Lancaster-road, Didsbury, Manchester, Henry Ashby, M.D., aged 62 years.

ROCK.—At 5, Manor-place, Edinburgh, suddenly, on July 6th, William John Brock, M.B., D.Sc. F.R.S.E., Medical Officer of Health for Midlothian, West Lothian, and Peebles-shire.

WYNN.—On July 1st, at St. Mary's House, Whitchurch, Salop, S. Tayleur Gwynn, M.D., in the 83rd year of his age.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE LANCET AND THE CURE OF CANCER.

To the Editor of THE LANCET.

SIR,—May I say, in reply to your strictures in your last issue, of my cure of cancer?

(1) When I cured my first case in 1903, I went up to London to tell my son-in-law, Dr. Gage-Brown, all about it. He simply replied, "The diet would kill the patient." To show England this was not so I trained a Lancashire working man to do a walk of 600 miles in ten days on the diet. The like was never done. I enclose an account of the training. You may study it and make as many inquiries as you like about it.

(2) There is a case of cancer cured in Brigstock—Herbert Crosby. You may see him and examine for yourself.

(3) Widow Neal of Burton Latimer, cured in 1903, said: "We shall now get the £20,000, and I shall have some of the money, and take a villa in Italy, and go and live there."

(4) I may say I was the first in the field to advocate the dietetic method as the right treatment of disease. I am glad to see, however, that both in this country and in America many are following it to-day.

(5) Dr. Robert Bell, late senior physician of the Women's Hospital, Glasgow, lecturing in Caxton Hall a few months ago, reported by the *Morning Post*, claimed the dietetic method as the only treatment for cancer. This he did after repudiating 15 years' experience in operations.

(6) Dr. Elmers Lee, 137, West 58th-street, New York, says the dietetic method is the only successful one. Others say the same.

(7) True, it follows that "Cancer Research," "Listerism," "Notification," "Isolation," "Disinfection," the L.G.B., the need for our heavy rates and taxes, &c., &c., all go now for very little. This, however, is of small consideration in comparison with the boon that the cure of cancer and disease generally means.

May I ask you in all fairness, in the name of common honesty, in the interests of humanity, and particularly in the name of truth, to publish this letter? I am, Sir, your obedient servant,

Brigstock, Thrapston, July 2nd, 1908. J. P. SANDLANDS.

⁂ We publish Mr. Sandlands's letter because he urges us to do so in the name of truth, but we would ask him to consider his own responsibilities towards truth. On the strength of what he calls "cures," he is urging the public to disbelieve in the whole system of scientific medicine. He may not know that he is ranging himself on the side of falsehood, his words may be inspired by honest belief; but he comes by his belief because his faith in himself is colossal and because his knowledge of medicine is *nil*. He incloses us a little pamphlet purporting to describe how he trained a working man to become an athlete. It is a glorification of himself—"My eyes have been opened and I have been labouring hard and long at this business. It would be a strange thing if I should miss the mark." And again—"I know from the best of reasons—experience—that it [disease] is nothing but that which we put into our stomachs. The cause of all our diseases is there." We learn of Mr. Sandlands's acumen as a veterinary surgeon—how he cured the baker's horse and taught two colonials to pasture their cattle properly, but we do not see one word in the pamphlet which supports Mr. Sandlands's claims to be a cancer curer. The pamphlet appears to be written in advertisement of certain composts of fruit and nuts which are advertised on its cover and we have no question to ask concerning it.—ED. L.

SIC VOS NON VOBIS.

To the Editor of THE LANCET.

SIR,—Some recent discussions over the Patents Acts induce me to offer some remarks on the simplicity of our profession in placing free, gratis, and all for nothing at the disposal of the public the products of our brains. Science and humanity are all very fine in their way, but this thing may be, and is being, carried too far. I read myself, or rather I presented, a paper at the Glasgow meeting of the British Medical Association in the "eighties" which dealt with the then fundamental defect in the preparation of meat juices. The paper made a fortune for several English companies, but when I appealed to them for some compensation they refused me any, though they could afford to advertise a column of my paper in the pages of THE LANCET for nearly the round of a year. Have not numbers of our profession the same story to tell, and is not all this a very great grievance? The sums which have been made by one great English company alone through and by my paper tot up to hundreds of thousands of pounds in a single year, and not even a crumb could they spare for Your obedient servant,

Cashel, July 4th, 1903. THOMAS LAFFAN.

⁂ We fear that we cannot sympathise with Mr. Laffan in his complaint, but we publish it at his desire. A medical man reading a paper at a medical congress has as his aim the education of his *confrères* and the benefit of the public by the improvement of medical knowledge. Mr. Laffan has no claim, moral or sentimental, upon these hundreds of thousands of pounds of income or upon the fortunes of the several English companies, even though these may have been created by his pen.—ED. L.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol. I. of 1908, which was completed with the issue of June 27th, and the Title-page to the Volume, were given in THE LANCET of July 4th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1908 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

A BOGUS MEDICAL MAN.

At the Essex assizes held at Chelmsford last month one Charles Cubben was sentenced to five years' penal servitude for bigamy. He was duly described in the press as "a doctor," but he had no right to such a style. His ingenious practice was to assume the names of persons whose address was given in the Medical Directory and Register as being abroad and then to masquerade as a practitioner. He appears to have done this for years, having on two occasions been fined for giving false medical certificates. It does not seem possible to protect the public from this particular kind of fraud. When a person whose name is not on the Register professes to have medical skill and imposes upon the public thereby we can have no sympathy with the public. It is only necessary to consult the Medical Register to expose the false pretence. But when, as in Cubben's case, the name of a duly registered medical practitioner is assumed the situation is a difficult one to deal with.

THE CAUSATION OF SEX.

To the Editor of The Lancet.

Sir,—In The Lancet of Jan. 21st, 1905 (p. 188), a letter headed as above and signed "Medicus Alter" appeared. Can you give me the name and address of the writer, as I might be glad to communicate with him.

I am, Sir, yours faithfully,
July 4th, 1908. N. E.

*** We publish the above on the chance that it may catch the eye of "*Medicus Alter*," *whose identity is lost to us at this lapse of time.*—Ed. L.

COUNTRY IN TOWN EXHIBITION.

The object of the Country in Town Exhibition, the third of its kind, which was opened by the Poet Laureate, Mr. Alfred Austin, at the Whitechapel Art Gallery on July 2nd, is primarily to show what may be done to cultivate flowers in town gardens, especially those of the east end of London, and thus to brighten the lives of many who by reason of social and economic conditions are compelled to spend their lives in an ugly environment. From this point of view the exhibition leaves nothing to be desired, though, taken as a whole, the two previous exhibitions possessed more attractive features. An interesting exhibit in the present exhibition is the large model of an open-air school designed for 100 children. The model is roughly on the scale of half an inch to a foot and shows the position and new type of class-rooms, verandahs, sleeping sheds, dining shed and kitchen, assembly shed, offices and baths, and the general plan of the grounds. Photographs of the model can be had for 1*s.*, and a leaflet describing the nature and object of open-air schools, with full details of the buildings, dimensions, and estimates, for 1*d.* The catalogue is also well worth the penny which is charged for it, as it contains a variety of information useful to naturalists and school teachers. The honorary secretary of the exhibition, which is open daily from noon to 9.30 p.m., with the exception of the last day of the exhibition, July 16th, when 8 p.m. has been fixed as the closing hour, is Mr. H. E. Turner, 1, Grosvenor Park, Camberwell, S.E., from whom further information can be obtained.

LOSS OF TASTE.

To the Editor of The Lancet.

Sir,—*One of my patients* has been *puzzling* me for some time He has complete loss of taste and refuses food. Would any one of your. readers who have had similar experience give me advice?

I am, Sir, yours faithfully,
Αθηναιος.

EAST COAST HOLIDAYS.

An attractive little handbook with artistic coloured pictures and maps of holiday resorts which are served by the *Great Eastern Railway* Company has been written by Mr. Percy Lindley, and published at 30, Fleet-street, London, E.C. A list of eastern counties golf links and particulars of fishing and yachting are appended as well as a section entitled "From East Coast to Continent." The coloured pictures are good; the artist has pourtrayed the sentiment of the scenes rather than their reality and *has been successful in his* imagining.

◆

Anxious is strongly *advised to* have no dealings with a well-known charlatan.

Mr. R. W. Bruce describes a very common sensation.

Communications not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Hull Times, Hull Mail, Daily Chronicle, Notts Express, Sheffield Telegraph, Wolverhampton Express, The Observer, Manchester Dispatch, Manchester Evening Chronicle, Bradford Observer, Birmingham Dispatch, Yorks Evening Post, Dundee Observer, Dundee Advertiser, Weekly Dispatch, Norfolk Standard, Manchester City News, Westminster Gazette, The Star, Daily Telegraph, Daily News, Electrical Engineering, Local Government Officer, Glasgow Evening Citizen, Morning Advertiser, Glasgow Evening News, Shrewsbury Record, Saturday Review, Scientific American (New York), &c.*
